A GEOMETRIC VERSION OF BGP REFLECTION FUNCTORS

STEFAN WOLF

Abstract. Quiver Grassmannians and quiver flags are natural generalisations of usual Grassmannians and flags. They arise in the study of quiver representations and Hall algebras. In general, they are projective varieties which are neither smooth nor irreducible.

We use a scheme theoretic approach to calculate their tangent space and to obtain a dimension estimate similar to the one of Reineke in [Rei02]. Using this we can show that if there is a generic representation, then these varieties are smooth and irreducible. If we additionally have a counting polynomial we deduce that their Euler characteristic is positive and that the counting polynomial evaluated at zero yields one.

After having done so, we introduce a geometric version of BGP reflection functors which allows us to deduce an even stronger result about the constant coefficient of the counting polynomial. We use this to obtain an isomorphism between the Hall algebra at $q = 0$ and Reineke's generic extension monoid in the Dynkin case.

One of the first non-trivial varieties one studies when learning algebraic geometry is the Grassmannian. It consists of r-dimensional subspaces of a fixed d-dimensional vector space V. The (vector space) Grassmannian is smooth and irreducible, has a nice functor of points and the tangent space at an r-dimensional subspace U of V is given by linear maps from U to V/U. A first generalisation of this variety is the flag variety, which consists of a filtration of V by subvector spaces of fixed dimension vectors.

Although the vector space Grassmannian already leads to interesting geometrical problems, it is still very easy. A generalisation is given by taking quiver Grassmannians. A quiver Q is an oriented graph and a k-representation of Q is given by assigning a k-vector space to each vertex of Q and a k-linear map between these vector spaces to each arrow of Q. The dimension vector of a finite dimensional k-representation M is the tuple of dimensions of the vector spaces at the vertices. For a k-representation M the quiver Grassmannian consists of subrepresentations of M of dimension vector $\underline{d}$. In general, this scheme is much more complex, or interesting, as the vector space Grassmannian. It is generally neither smooth nor reduced nor irreducible. Studying the quiver Grassmannian was first done by Schofield [Sch92] when he introduced a calculus of Schur roots. Recently it received attention for example by Caldero and Chapoton [CC06] when they showed that its Euler characteristic gives coefficients in the cluster algebra. Caldero and Reineke [CR] showed that the Euler characteristic is positive provided that the quiver is acyclic and that the representation is rigid by using Lusztig's pervese sheaf approach [Lus93] to quantum groups. There is also the natural generalisation to quiver flags, but up to now there has been no work investigating geometric properties of those.

2000 Mathematics Subject Classification. 16G20, 14L30.

The first part of this paper deals with a geometric analysis of quiver flags and quiver Grassmannians. We introduce their functors of points and calculate their tangent spaces. In order to do this for the quiver flag we use a generalisation of tensor algebras. Then we use this information and Chevalley's theorem to obtain a dimension estimate for the quiver flag similar to the one of Reineke [Rei02] for quiver Grassmannians, but here it holds not only in characteristic 0. Afterwards, we use this to show smoothness and irreducibility of the quiver flag if there is a generic representation. Finally, under this assumption and additionally having a counting polynomial, we obtain the positivity of the Euler characteristic and that the constant term of the counting polynomial is 1.

There is Ringel's Hall algebra approach to quantum groups [Rin90a]. He generalised a construction of Steinitz [Ste01] and Hall [Hal59] to obtain an associative algebra structure on the $\mathbb{Q}$-vector space $\mathcal{H}_k(Q)$ with basis the isomorphism classes of representations of Q over a finite field k, the Ringel-Hall algebra. The structure constants are given by counting numbers of subrepresentations having a fixed isomorphism class such that the quotient also has a fixed isomorphism class.

The whole Ringel-Hall algebra is generally too complicated, and therefore one introduces the $\mathbb{Q}$-subalgebra $\mathcal{C}_k(Q)$ generated by the isomorphism classes of simple representations without self-extensions. The coefficients of a representation in the product of a sequence of simples is given by the number of k-valued points of a certain quiver flag variety, therefore counting rational points of these varieties is crucial there. There is a generic version $\mathcal{C}_q(Q)$, a $\mathbb{Q}[q]$-algebra, such that specialising q to $|k|$ recovers $\mathcal{C}_k(Q)$. Ringel's paper [Rin90a], for the Dynkin case, and later Green's paper [Gre95] combined with a result of Sevenhant and Van Den Bergh [SVDB01], for the general case, yield that, after twisting the multiplication with the Euler form of Q, the generic composition algebra $\mathcal{C}_q(Q) \otimes \mathbb{C}(q)$ is isomorphic to the positive part of the quantised enveloping algebra of the Kac-Moody Lie algebra corresponding to Q.

Reineke [Rei02] showed that one has a monoid structure on the set of irreducible closed subvarieties of the representation variety. The multiplication is given by taking all possible extensions. This monoid is called the generic extension monoid $\mathcal{M}(Q)$. Similarly to the Hall algebra, it is in general too complicated, so one restricts itself to the submonoid generated by the orbits of simple representations without self-extensions, the composition monoid $\mathcal{CM}(Q)$. The elements of the composition monoid are the varieties consisting of representations having a composition series with prescribed composition factors in prescribed order and are therefore closely related to quiver flags.

For the generic composition algebra viewed as a $\mathbb{Q}(v)$-algebra with $v^2 = q$ the (twisted) quantum Serre relations are defining as shown in [Rin96]. Reineke showed that the quantum Serre relations specialised to $q = 0$ hold in the composition monoid. They are in general not defining any more if we specialise q to 0 in the composition algebra. But nonetheless one can conjecture, as Reineke did in [Rei01] and [Rei02], that there is a homomorphism of $\mathbb{Q}$-algebras

$$\Phi\colon \mathcal{C}_0(Q) \to \mathbb{Q}\mathcal{CM}(Q)$$

sending simples to simples and therefore being automatically surjective.

The first step in this direction was done by Hubery [Hub05] showing that for the Kronecker quiver

$$K = \begin{tikzcd} \bullet \arrow[r, shift left] \arrow[r, shift right] & \bullet \end{tikzcd}$$

Φ is a homomorphism of $\mathbb{Q}$-algebras with non-trivial kernel. He did this by calculating defining relations for $\mathcal{C}_0(K)$ and $\mathcal{CM}(K)$. He also was able to give generators for the kernel of Φ.

In order to get further results in this direction, we need to calculate many of the structure coefficients in the composition algebra. These are given by counting k-valued points of quiver flags of a representation M over finite fields k. For this, we develop a framework for applying reflection functors to quiver flags. We give a stratification of the flag into locally closed subschemes such that on each strata we can nicely apply reflection functors. We will see that this operations does not change the number of k-valued points modulo the number of elements of the field k. Using this, we can immediately show that for the Dynkin case the coefficients at $q = 0$ are one or zero and by this we obtain immediately that $\mathcal{C}_0(Q)$ and $\mathbb{Q}\mathcal{CM}(Q)$ are isomorphic.

1. Geometric setup

We want to define some functors from commutative rings to sets which are schemes, ending up with the quiver Grassmannian. These should turn out to be useful to define morphisms between schemes naturally coming up in representation theory of quivers. All of this section should be standard. We say that a scheme X over some field k is a variety if it is separated, noetherian and of finite type over k. The main reference for the geometric methods is [DG70].

For a commutative ring R and an R-module P we say that P has rank r if for every prime $\mathfrak{p} \in \operatorname{Spec} R$ we have that the localisation $P_{\mathfrak{p}}$ is free of rank r as an $R_{\mathfrak{p}}$-module. As a consequence P is projective. Let $d, e, r \in \mathbb{N}$. We define various schemes via their functors of points from commutative rings to sets. Let R be a commutative ring. We define

$$\begin{aligned}
\operatorname{Hom}(d,e)(R) &:= \operatorname{Hom}_R(R^d, R^e), \\
\operatorname{Hom}(d,e)_r(R) &:= \left\{ f \in \operatorname{Hom}(d,e)(R) \;\middle|\; \begin{array}{l} \operatorname{Im} f \text{ is a direct summand} \\ \text{of } R^e \text{ of rank}\, r \end{array} \right\}, \\
\operatorname{Inj}(d, d+e)(R) &:= \{\, f \in \operatorname{Hom}(d, d+e)(R) \mid f \text{ is a split injection} \,\} \\
&= \operatorname{Hom}(d, d+e)_d(R)
\end{aligned}$$

and

$$\begin{aligned}
\operatorname{Surj}(d+e, e)(R) &:= \{\, g \in \operatorname{Hom}(d+e, e)(R) \mid g \text{ is surjective} \,\} \\
&= \operatorname{Hom}(d+e, e)_e(R).
\end{aligned}$$

We define the Grassmannian scheme via its functor of points

$$\operatorname{Gr}\binom{d+e}{d}(R) := \left\{\, P \subset R^{d+e} \;\middle|\; P \text{ is a direct summand of rank}\, d \,\right\}.$$

If $\boldsymbol{d} = (d^0, \ldots, d^\nu)$ is a sequence of integers, we define the flag scheme $\mathrm{Fl}(\boldsymbol{d}) \subset \prod \mathrm{Gr}\binom{d^\nu}{d^i}$ as

$$\mathrm{Fl}(\boldsymbol{d})(R) := \left\{ (U^0, \ldots, U^\nu) \in \prod_{i=0}^{\nu} \mathrm{Gr}\binom{d^\nu}{d^i}(R) \;\middle|\; \begin{array}{c} U^i \subset U^{i+1} \text{ for} \\ \text{all } 0 \leq i < \nu \end{array} \right\}.$$

Let $n \in \mathbb{N}$. We define the group scheme GL_n via its functor of points

$$\mathrm{GL}_n(R) := \mathrm{GL}(R^n).$$

Lemma 1.1. Let $d, e, r \in \mathbb{N}$ and $\boldsymbol{d} = (d^0, \ldots, d^\nu)$ a sequence of integers. Then

(1) $\mathrm{Hom}(d, e)$ is an affine space.
(2) $\mathrm{Hom}(d, e)_r$ is a locally closed subscheme of $\mathrm{Hom}(d, d+e)$.
(3) $\mathrm{Inj}(d, d+e)$ is an open subscheme of $\mathrm{Hom}(d, d+e)$.
(4) $\mathrm{Surj}(d+e, e)$ is an open subscheme of $\mathrm{Hom}(d+e, e)$.
(5) $\mathrm{Gr}\binom{d+e}{d}$ and $\mathrm{Fl}(\boldsymbol{d}) \subset \prod \mathrm{Gr}\binom{d^\nu}{d^i}$ are projective schemes, smooth over $\mathbb{Z}$.
(6) GL_n is a smooth group scheme over $\mathbb{Z}$.
(7) The projection $\mathrm{Inj}(d, d+e) \to \mathrm{Gr}\binom{d+e}{d}$ sending each f to $\mathrm{Im}(f)$ is a principal GL_d-bundle, locally trivial in the Zariski topology.

Proof. For (1)–(4) and (7) see, for example, [CB96a]. For (5) and (6) see [DG70]. □

Now we generalise these schemes to quivers. For standard notations and results about quivers we refer the reader to [Rin84]. A quiver $Q = (Q_0, Q_1, s, t)$ is a directed graph with a set of vertices Q_0, a set of arrows Q_1 and maps $s, t \colon Q_1 \to Q_0$, sending an arrow to its starting respectively terminating vertex. In particular, we write $\alpha \colon s(\alpha) \to t(\alpha)$ for an $\alpha \in Q_1$. A quiver Q is finite if Q_0 and Q_1 are finite sets. In the following, all quivers will be finite. For a quiver $Q = (Q_0, Q_1, s, t)$ we define $Q^{op} := (Q_0, Q_1, t, s)$ as the quiver with all arrows reversed.

A path of length $r \geq 0$ in Q is a sequence of arrows $\xi = \alpha_1\alpha_2 \cdots \alpha_r$ such that $t(\alpha_i) = s(\alpha_{i+1})$ for all $1 \leq i < r$. We write $t(\xi) := t(\alpha_r)$ and $s(\xi) := s(\alpha_1)$.

For each $i \in Q_0$ there is the trivial path ϵ_i of length zero starting and terminating in the vertex i. We identify the elements of Q_0 with paths of length 0. We denote by $Q(i, j)$ the set of paths starting at the vertex i and terminating at the vertex j.

If R is a ring, then the path algebra RQ has as basis the set of paths and the multiplication $\xi \cdot \zeta$ is given by the concatenation of paths if $t(\xi) = s(\zeta)$ or zero otherwise. In particular, the ϵ_i are pairwise orthogonal idempotents of RQ, that is $\epsilon_i\epsilon_j = \delta_{ij}\epsilon_i$.

Let Q_r denote the set of paths of length r. This extends the notation of vertices Q_0 and arrows Q_1. Then

$$RQ = \bigoplus_{r \geq 0} RQ_r,$$

where RQ_r is the free R-module with basis the elements of Q_r. By construction,

$$RQ_r RQ_s = RQ_{r+s},$$

thus RQ is an $\mathbb{N}$-graded R-algebra.

We define a partial order on $\mathbb{Z}Q_0$ by $\underline{d} = \sum_i d_i\epsilon_i \geq 0$ if and only if $d_i \geq 0$ for all $i \in Q_0$. An element $\underline{d} \in \mathbb{Z}Q_0$ is called a dimension vector. We endow $\mathbb{Z}Q_0$ with a bilinear form $\langle \cdot\,, \cdot \rangle_Q$ defined by

$$\langle \underline{d}\,, \underline{e} \rangle_Q := \sum_{i \in Q_0} d_i e_i - \sum_{\alpha\colon i \to j \in Q_1} d_i e_j .$$

This form is generally called the Euler form or the Ringel form. We also define its symmetrisation

$$(\underline{d}\,, \underline{e})_Q := \langle \underline{d}\,, \underline{e} \rangle_Q + \langle \underline{e}\,, \underline{d} \rangle_Q .$$

Let Q be a quiver and k be a field. A k-representation M of Q is given by finite dimensional k-vector spaces M_i for each $i \in Q_0$ and k-linear maps $M_\alpha\colon M_i \to M_j$ for each $\alpha \in Q_1$. If M and N are k-representations of Q, then a morphism $f\colon M \to N$ is given by k-linear maps $f_i\colon M_i \to N_i$ for each $i \in Q_0$ such that the following diagram commutes

$$\begin{tikzcd}
M_i \arrow[r, "M_\alpha"] \arrow[d, "f_i"'] & M_j \arrow[d, "f_j"] \\
N_i \arrow[r, "N_\alpha"'] & N_j
\end{tikzcd}$$

for all $\alpha\colon i \to j \in Q_1$. Denote by $\operatorname{rep}(Q, k)$ the category of finite dimensional k-representations of Q.

We will use the following notations for a k-algebra Λ and two finite dimensional Λ-modules M and N:

- $(M, N)_\Lambda := \operatorname{Hom}_\Lambda(M, N)$,
- $(M, N)^i_\Lambda := \operatorname{Ext}^i_\Lambda(M, N)$,
- $[M, N]_\Lambda := \dim_k \operatorname{Hom}_\Lambda(M, N)$,
- $[M, N]^i_\Lambda := \dim_k \operatorname{Ext}^i_\Lambda(M, N)$.

Note that $[M, N]^0 = [M, N]$ and $(M, N)^0 = (M, N)$. If Q is a quiver, we define $(M, N)_Q := (M, N)_{kQ}$ if M and N are k-representations and similarly for the other notations. For dimension vectors $\underline{d}$ and $\underline{e}$ we denote by $\hom_{kQ}(\underline{d}, \underline{e})$ the minimal value of $[M, N]_Q$ for $M \in \operatorname{Rep}_Q(\underline{d}, k)$ and $N \in \operatorname{Rep}_Q(\underline{e}, k)$ and similarly for $\operatorname{ext}^i_{kQ}(\underline{d}, \underline{e})$. More generally, if $\mathcal{A}$ and $\mathcal{B}$ are subsets of $\operatorname{Rep}_Q(\underline{d}, k)$ and $\operatorname{Rep}_Q(\underline{e}, k)$ respectively, then $\hom(\mathcal{A}, \mathcal{B})$ and $\operatorname{ext}^i(\mathcal{A}, \mathcal{B})$ are defined analogously. Whenever the algebra, the field or the quiver is clear from the context, we omit them from the notation. If our algebra is hereditary we denote Ext^1 by Ext.

Let M be a k-representation. A sequence of dimension vectors $\underline{\boldsymbol{d}} = (\underline{d}^0, \ldots, \underline{d}^\nu)$ is called a filtration of M, or of $\underline{\dim}\, M$, if $\underline{d}^i \leq \underline{d}^{i+1}$, $\underline{d}^0 = 0$ and $\underline{d}^\nu = \underline{\dim}\, M$.

Let Q be a quiver, $\underline{d}$ and $\underline{e}$ dimension vectors and $\underline{\boldsymbol{d}} = (\underline{d}^0, \ldots, \underline{d}^\nu)$ a filtration. By taking fibre products we can generalise the previous constructions and define $\operatorname{Hom}(\underline{d}, \underline{e})$, $\operatorname{Inj}(\underline{d}, \underline{d} + \underline{e})$, $\operatorname{Surj}(\underline{d} + \underline{e}, \underline{e})$, $\operatorname{Gr}\binom{\underline{d}+\underline{e}}{\underline{d}}$, $\operatorname{Fl}(\underline{\boldsymbol{d}})$ and $\operatorname{GL}_{\underline{d}}$ pointwise. For all above schemes we can do base change to any commutative ring k, and we will denote these schemes by e.g. $\operatorname{Hom}(\underline{d}, \underline{e})_k$.

Definition 1.2. Define the representation scheme

$$\operatorname{Rep}_Q(\underline{d}) := \prod_{\alpha : i \to j} \operatorname{Hom}(d_i, d_j).$$

This is isomorphic to an affine space. Moreover, $\operatorname{GL}_{\underline{d}}$ acts by base change on $\operatorname{Rep}_Q(\underline{d})$.

Remark 1.3. For each scheme defined for a quiver Q we often omit the index if Q is obvious, e.g. $\operatorname{Rep}(\underline{d}) = \operatorname{Rep}_Q(\underline{d})$.

More generally, we have the module scheme.

Definition 1.4. Let k be a field, Λ a finitely generated k-algebra and

$$\rho\colon k\langle x_1, \ldots, x_m\rangle \to \Lambda$$

a surjective map from the free associative algebra to Λ. The affine k-scheme $\operatorname{Mod}_\Lambda(d)$ is defined by

$$\operatorname{Mod}_\Lambda(d)(R) = \left\{ (M^1, \ldots, M^m) \in (\operatorname{End}(R^d))^m \;\middle|\; \begin{array}{c} f(M^1, \ldots, M^m) = 0 \\ \forall\ f \in \operatorname{Ker}\rho \end{array} \right\}.$$

There is a natural GL_d-action on $\operatorname{Mod}_\Lambda(d)$ given by conjugation.

Remark 1.5. We have that $\operatorname{Mod}_\Lambda(d)$ is isomorphic to the functor

$$R \mapsto \operatorname{Hom}_{R-alg}(\Lambda \otimes R, \operatorname{End}(R^d)).$$

Therefore, another choice of ρ gives an isomorphic scheme.

Let $\{\epsilon_i\}_{i\in I}$, I some index set, be a complete set of (not necessarily primitive) orthogonal idempotents for Λ. We say that a Λ-module M has dimension vector $\underline{d} = \sum d_i\epsilon_i \in \mathbb{N}^I$ with respect to this idempotents, if $\dim M_i = \dim M\epsilon_i = d_i$. The subscheme $\operatorname{Mod}_\Lambda(\underline{d})$ consisting of Λ-modules of dimension vector $\underline{d}$ is an open and closed subscheme of $\operatorname{Mod}_\Lambda(d)$, therefore

$$\operatorname{Mod}_\Lambda(d) = \coprod \operatorname{Mod}_\Lambda(\underline{d}).$$

Let Q be a quiver, k a field, d an integer and $\underline{d}$ a dimension vector such that $\sum d_i = d$. Then, after choosing an isomorphism $\bigoplus k^{d_i} \to k^d$, there is a natural immersion

$$\operatorname{Rep}_Q(\underline{d}) \to \operatorname{Mod}_{kQ}(\underline{d}) \subset \operatorname{Mod}_{kQ}(d).$$

Note that $\mathrm{GL}_{\underline{d}}(k)$-orbits in $\operatorname{Rep}_Q(\underline{d})(k)$ are in one-to-one correspondence with isomorphism classes of k-representations of dimension vector $\underline{d}$. Similarly, $\mathrm{GL}_d(k)$-orbits in $\operatorname{Mod}_\Lambda(d)(k)$ are in one-to-one correspondence with isomorphism class of Λ-modules of k-dimension d.

We define now quiver flags and quiver Grassmannians as varieties. Choose a k-representation $M \in \operatorname{Rep}_Q(\underline{d} + \underline{e})(k)$. We set

$$\operatorname{Gr}_Q \binom{M}{\underline{d}}(R) := \left\{ U \in \operatorname{Gr} \binom{\underline{d} + \underline{e}}{\underline{d}}_k (R) \;\middle|\; \begin{array}{c} U \text{ is a subrepesentation of} \\ M \otimes_k R \end{array} \right\}$$

for each k-algebra R. Then $\operatorname{Gr}_Q \binom{M}{\underline{d}}$ is a closed subscheme of $\operatorname{Gr}\binom{\underline{d}+\underline{e}}{\underline{d}}_k$ and therefore projective. In a similar way we obtain a closed subscheme $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ of $\operatorname{Fl}(\underline{\boldsymbol{d}})_k$ for a filtration $\underline{\boldsymbol{d}}$ of M.

Let Λ be a k-algebra and d, e two integers. For a Λ-module $M \in \operatorname{Mod}_\Lambda(d + e)$ we define

$$\operatorname{Gr}_\Lambda \binom{M}{d}(R) := \left\{ U \in \operatorname{Gr} \binom{d + e}{d}(R) \;\middle|\; U \text{ is a submodule of } M \otimes_k R \right\}.$$

Again, for some set of idempotents $\{\epsilon_i\}$ we define $\mathrm{Gr}_\Lambda\binom{M}{\underline{d}}$ as the subscheme consisting of submodules having dimension vector $\underline{d}$ and obtain

$$\mathrm{Gr}_\Lambda\binom{M}{d} = \coprod \mathrm{Gr}_\Lambda\binom{M}{\underline{d}},$$

each $\mathrm{Gr}_\Lambda\binom{M}{\underline{d}}$ being open and closed in $\mathrm{Gr}_\Lambda\binom{M}{d}$. Moreover, for $\Lambda = kQ$ we obtain that

$$\mathrm{Gr}_Q\binom{M}{\underline{d}} \cong \mathrm{Gr}_{kQ}\binom{M}{\underline{d}}$$

via the immersion $\mathrm{Rep}_Q(\underline{d}) \to \mathrm{Mod}_{kQ}(\underline{d})$.

We have the following well-known result.

Proposition 1.6. Let X, Y be two schemes, Y being irreducible. Let $f\colon X \to Y$ be a morphism of schemes such that f is open and for each $z \in Y$ the fibre $f^{-1}(z)$ is irreducible. Then X is irreducible.

Proof. Take $\emptyset \neq U, V \subset X$ and U, V open. We need to show that $U \cap V$ is non-empty. We know that $f(U)$ and $f(V)$ are non-empty and open in Y. Therefore, they intersect non-trivially. Let $y \in f(U) \cap f(V)$. By definition, we have that $U \cap f^{-1}(y) \neq \emptyset$ and $V \cap f^{-1}(y) \neq \emptyset$ and both are open in $f^{-1}(y)$. By assumption, the fibre $f^{-1}(y)$ is irreducible and therefore $U \cap V \cap f^{-1}(y) \neq \emptyset$ and we are done. □

Remark 1.7. The same is true for arbitrary topological spaces, since the proof relies purely on topology.

2. Tangent spaces

Let k be a field and Λ a finitely generated k-algebra. We want to calculate the tangent space at a point of $\mathrm{Gr}_\Lambda\binom{M}{d}$.

Lemma 2.1. Let $d, e \in \mathbb{N}$, k a field, Λ a finitely generated k-algebra and $M \in \mathrm{Mod}_\Lambda(d+e)(k)$. Let $U \in \mathrm{Gr}_\Lambda\binom{M}{d}(K)$, for a field extension K of k. Then

$$T_U \,\mathrm{Gr}_\Lambda\binom{M}{d} \cong \mathrm{Hom}_{\Lambda\otimes_k K}(U, (M \otimes_k K)/U).$$

Proof. In this proof we use left modules since the notation is more convenient. For the tangent space we use the definition of [DG70, I, §4, no 4]. By base change, we can assume that $K = k$. We prove the claim by doing a $k[\varepsilon]$-valued point calculation ($\varepsilon^2 = 0$). The short exact sequence

$$\begin{tikzcd} 0 \arrow[r] & U \arrow[r, "\iota"] & M \arrow[r, "\pi"] \arrow[l, dotted, bend left, "p"] & M/U \arrow[r] \arrow[l, dotted, bend left, "j"] & 0 \end{tikzcd}$$

is split in the category of k-vector spaces, therefore there is a retraction p of ι and a section j of π. We consider elements of U as elements of M via the inclusion ι.

The map $k[\varepsilon] \to k$ given by $s + r\epsilon \mapsto s$ induces a map $\theta\colon V \otimes k[\varepsilon] \to V$ for each k-vector space V.

For each homomorphism $f \in \mathrm{Hom}_\Lambda(U, M/U)$ we define

$$S_f := \{\, u + v\varepsilon \mid u \in U,\ \pi(v) = f(u) \,\} \subset M \otimes k[\varepsilon].$$

Note that $\theta(S_f) = U$. We need to show that $S_f \in \mathrm{Gr}_{\Lambda\otimes k[\varepsilon]}\binom{M\otimes k[\varepsilon]}{d}$ and that every element S of the Grassmannian with $\theta(S) = U$ arises in this way.

First, we show that S_f is a $\Lambda \otimes k[\varepsilon]$-submodule. Let $u + v\varepsilon \in S_f$ and $r + s\varepsilon \in \Lambda \otimes k[\varepsilon]$. Then we have

$$(r + s\varepsilon)(u + v\varepsilon) = ru + (rv + su)\varepsilon.$$

Since $\pi(v) = f(u)$, $u \in U$ and f is a Λ-homomorphism we obtain that

$$\pi(rv + su) = r\pi(v) = rf(u) = f(ru).$$

Therefore, S_f is a $\Lambda \otimes k[\varepsilon]$ submodule.

Now we show that S_f is, as a $k[\varepsilon]$-module, a summand of $M \otimes k[\varepsilon]$ of rank d. Let $\tilde{f} \in \operatorname{Hom}_k(U, M) := j \circ f$ be a k-linear lift of f.Let

$$\begin{aligned} \phi\colon \quad & U \otimes k[\varepsilon] \to M \otimes k[\varepsilon] \\ & u + v\varepsilon \mapsto u + (\tilde{f}(u) + v)\varepsilon. \end{aligned}$$

Obviously, ϕ is $k[\varepsilon]$-linear and $\operatorname{Im} \phi = S_f$. Moreover, ϕ is split with retraction

$$\begin{aligned} \psi\colon \quad & M \otimes k[\varepsilon] \to U \otimes k[\varepsilon] \\ & x + y\varepsilon \mapsto p(x) + p(y - \tilde{f} \circ p(x))\varepsilon. \end{aligned}$$

Therefore, S_f is a summand of $M \otimes k[\varepsilon]$ of rank d.

On the other hand, let $S \in \operatorname{Gr}_{\Lambda \otimes k[\varepsilon]} \binom{M \otimes k[\varepsilon]}{d}$ such that $\theta(S) = U$. Then, $U\varepsilon$ is a k-subspace of S with $\dim_k U\varepsilon = d$, therefore $\dim_k S/(U\varepsilon) = d$. The map sending $u + v\varepsilon \in S$ to $u \in U$ is surjective, therefore the induced map from $S/(U\varepsilon)$ is an isomorphism. Hence, for each $u \in U$ there is a $v \in M$, such that $u + v\varepsilon \in S$ and v is unique up to a element in $U\varepsilon$. Set $f(u) := \pi(v)$ and, by the discussion before, this does not depend on the choice of v and we have that $S = S_f$. Moreover, $f \in \operatorname{Hom}_\Lambda(U, M/U)$: Let $r \in \Lambda$, $u \in U$ and $v \in M$, such that $u + v\varepsilon \in S$. Then, $ru + rv\varepsilon \in S$. By definition, $f(ru) = \pi(rv) = r\pi(v) = rf(u)$. □

3. Tensor algebras

We now want to calculate the tangent space at the quiver flag variety by using the previous result on the tangent space at the module Grassmannian. For this we use tensor algebras, or more precisely a generalisation of them.

Let Λ_0 be a ring and Λ_1 a Λ_0-bimodule. Define the tensor ring $T(\Lambda_0, \Lambda_1)$ to be the $\mathbb{N}$-graded Λ_0-module

$$\Lambda := \bigoplus_{r \geq 0} \Lambda_r, \quad \Lambda_r := \Lambda_1 \otimes_{\Lambda_0} \cdots \otimes_{\Lambda_0} \Lambda_1 \ (r \text{ times}),$$

with multiplication given via the natural isomorphism $\Lambda_r \otimes_{\Lambda_0} \Lambda_s \cong \Lambda_{r+s}$. If $\lambda \in \Lambda_r$ is homogeneous, we write $|\lambda| = r$ for its degree.

The graded radical of Λ is the ideal $\Lambda_+ := \bigoplus_{r \geq 1} \Lambda_r$. Note that $\Lambda_+ \cong \Lambda_1 \otimes_{\Lambda_0} \Lambda$ as right Λ-modules.

Lemma 3.1. Let R and S be rings. Let A_R, ${}_R B_S$ and C_S be modules over the corresponding rings. Assume that ${}_R B_S$ is S-projective and R-flat. Then

$$\operatorname{Ext}^n_S(A \otimes_R B, C) \cong \operatorname{Ext}^n_R(A, \operatorname{Hom}_S(B, C)).$$

Proof. Choose a projective resolution $P_\bullet$ of A_R. The functor $- \otimes_R B$ is exact, and for any projective module P_R the functor $\operatorname{Hom}_S(P \otimes_R B, -) \cong \operatorname{Hom}_R(P, -) \circ$

$\operatorname{Hom}_S(B_S, -)$ is exact since B_S is projective. Therefore, $P_\bullet \otimes_R B$ gives a projective resolution of $A \otimes_R B_S$ as an S-module. We obtain

$$\begin{aligned}\operatorname{Ext}^n_S(A \otimes_R B, C) &= H^n \operatorname{Hom}_S(P_\bullet \otimes_R B, C) \cong \\ &\cong H^n \operatorname{Hom}_R(P_\bullet, \operatorname{Hom}_S(B, C)) = \operatorname{Ext}^n_R(A, \operatorname{Hom}_S(B, C)).\end{aligned}$$

□

The following proof is the standard proof for showing that a "classical" tensor algebra, i.e. a tensor algebra where Λ_0 is semisimple, is hereditary.

Theorem 3.2. Let Λ be a tensor ring and $M \in \operatorname{Mod}\Lambda$. Then there is a short exact sequence

$$0 \to M \otimes_{\Lambda_0} \Lambda_+ \xrightarrow{\delta_M} M \otimes_{\Lambda_0} \Lambda \xrightarrow{\epsilon_M} M \to 0,$$

where, for $m \in M$, $\lambda \in \Lambda$ and $\mu \in \Lambda_1$,

$$\epsilon_M(m \otimes \lambda) := m \cdot \lambda,$$

$$\delta_M(m \otimes (\mu \otimes \lambda) := m \otimes (\mu \otimes \lambda) - m \cdot \mu \otimes \lambda.$$

Moreover, if ${}_{\Lambda_0}\Lambda_1$ is flat, then $\operatorname{pd} M \otimes_{\Lambda_0} \Lambda_+ \leq \operatorname{gldim} \Lambda_0$ and $\operatorname{pd} M \otimes_{\Lambda_0} \Lambda \leq \operatorname{gldim} \Lambda_0$.

Proof. It is clear that ϵ_M is an epimorphism and that $\epsilon_M \delta_M = 0$. To see that δ_M is a monomorphism, we decompose $M \otimes \Lambda = \bigoplus_{r \geq 0} M \otimes \Lambda_r$ and similarly $M \otimes \Lambda_+$ as Λ_0-modules. Then δ_M restricts to maps $M \otimes \Lambda_r \to (M \otimes \Lambda_r) \oplus (M \otimes \Lambda_{r-1})$ for each $r \geq 1$ and moreover acts as the identity on the first component. In particular, if $\sum_{r=1}^t x_r \in \operatorname{Ker}(\delta_M)$ with $x_r \in M \otimes \Lambda_r$, then $x_t = 0$. Thus δ_M is injective.

Next we show that $M \otimes \Lambda = (M \otimes \Lambda_0) \oplus \operatorname{Im}(\delta_M)$. Let $x = \sum_{r=0}^t x_r \in M \otimes \Lambda$. We show that $x \in (M \otimes \Lambda_0) + \operatorname{Im}(\delta_M)$ by induction on t. For $t = 0$ this is trivial. Let $t \geq 1$. Then $x_t \in M \otimes \Lambda_+$ and $x - \delta_M(x_t) = \sum_{r=0}^{t-1} x'_r$. So we are done by induction. If $x \in \operatorname{Im}(\delta_M) \cap M \otimes \Lambda_0$, then there is a $y \in M \otimes \Lambda_+$ such that $\delta_M(y) = x \in M \otimes \Lambda_0$. But this is only the case if $y = 0$ and therefore $x = 0$.

Now let ${}_{\Lambda_0}\Lambda_1$ be flat. Then ${}_{\Lambda_0}\Lambda$ is flat. If N is any Λ_0-module, then $\operatorname{pd}_\Lambda N \otimes \Lambda \leq \operatorname{pd}_{\Lambda_0} N$ since

$$\operatorname{Ext}^n_\Lambda(N \otimes \Lambda, L) \cong \operatorname{Ext}^n_{\Lambda_0}(N, \operatorname{Hom}_\Lambda(\Lambda, L)) = \operatorname{Ext}^n_{\Lambda_0}(N, L)$$

for any $L \in \operatorname{Mod}\Lambda$ by the lemma. Therefore, the second part follows since $\Lambda_+ = \Lambda_1 \otimes \Lambda$. □

Let R be any k-algebra of finite global dimension and let M, N be two R-modules. The Euler form of M with N is defined by

$$\langle M, N \rangle_R := \sum_{i=0}^{\infty} \dim_k \operatorname{Ext}^i(M, N).$$

Ringel showed that for a quiver Q and two k-representations M and N we have that

$$\langle M, N \rangle_Q = \langle M, N \rangle_{kQ}.$$

Now let Q be a quiver and $\Lambda_0 = R^{Q_0}$ for a fixed ring R. Let $\Lambda_1 := R^{Q_1}$ be the free Λ_0-bimodule given by the arrows. The tensor ring $T(\Lambda_0, \Lambda_1)$ is then equal to RQ. Note that $\{\epsilon_i\}_{i \in Q_0}$ is an orthogonal, complete set of idempotents. As before, for an RQ-module M we denote $M\epsilon_i$ by M_i. As R-modules we have that $M = \bigoplus M_i$.

Theorem 3.3. Let R be a k-algebra with $\operatorname{gldim} R = n < \infty$. Let M and N be two finite dimensional modules over RQ. Then the Euler form is given by

$$\langle M, N\rangle_{RQ} = \sum_{i\in Q_0} \langle M_i, N_i\rangle_R - \sum_{\alpha\colon i\to j} \langle M_i, N_j\rangle_R .$$

Proof. Let $\Lambda_0 = R^{Q_0}$. There is a natural Λ_0-bimodule structure on $\Lambda_1 = R^{Q_1}$. Let $\Lambda = T(\Lambda_0, \Lambda_1) = RQ$. Let $0 \to M \otimes_{\Lambda_0} \Lambda_1 \otimes_{\Lambda_0} \Lambda \to M \otimes_{\Lambda_0} \Lambda \to M \to 0$ be the short exact sequence of the previous theorem. Apply $\mathrm{Hom}(-, N)$ to it and consider the long exact sequence

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Hom}_\Lambda(M,N) \arrow[r] & \mathrm{Hom}_\Lambda(M\otimes_{\Lambda_0}\Lambda,N) \arrow[r] & \mathrm{Hom}_\Lambda(M\otimes_{\Lambda_0}\Lambda_1\otimes_{\Lambda_0}\Lambda,N) \arrow[dll, rounded corners] \\
& \mathrm{Ext}^1_\Lambda(M,N) \arrow[r] & \mathrm{Ext}^1_\Lambda(M\otimes_{\Lambda_0}\Lambda,N) \arrow[r] & \mathrm{Ext}^1_\Lambda(M\otimes_{\Lambda_0}\Lambda_1\otimes_{\Lambda_0}\Lambda,N) \\
& \cdots & & \\
{} \arrow[r] & \mathrm{Ext}^n_\Lambda(M,N) \arrow[r] & \mathrm{Ext}^n_\Lambda(M\otimes_{\Lambda_0}\Lambda,N) \arrow[r] & \mathrm{Ext}^n_\Lambda(M\otimes_{\Lambda_0}\Lambda_1\otimes_{\Lambda_0}\Lambda,N) \\
{} \arrow[r] & \mathrm{Ext}^{n+1}_\Lambda(M,N) \arrow[r] & 0. &
\end{tikzcd}$$

Here we obtain the last 0 since the $\operatorname{pd} M \otimes \Lambda \leq \operatorname{gldim} R$ by the previous theorem.

Now, since ${}_{\Lambda_0}\Lambda_\Lambda$ is projective as a Λ_0-module and as a Λ-module, we obtain

$$\mathrm{Ext}^i_\Lambda(M \otimes_{\Lambda_0} \Lambda, N) \cong \mathrm{Ext}^i_{\Lambda_0}(M, N) \cong \bigoplus_{i\in Q_0} \mathrm{Ext}^i_R(M_i, N_i)$$

and

$$\mathrm{Ext}^i_\Lambda(M \otimes_{\Lambda_0} \Lambda_1 \otimes_{\Lambda_0} \Lambda, N) \cong \mathrm{Ext}^i_{\Lambda_0}(M \otimes_{\Lambda_0} \Lambda_1, N) \cong \bigoplus_{\alpha\colon i\to j} \mathrm{Ext}^i_R(M_i, N_j).$$

This yields the claim. □

Remark 3.4. Note that, for a field k, we recover Ringel's result, namely that

$$\sum_{i\in Q_0} \dim M_i \dim N_i - \sum_{\alpha\colon i\to j} \dim M_i \dim N_j = [M, N]_{kQ} - [M, N]^1_{kQ}$$

for two k-representations M and N of a quiver Q.

4. Geometry of Quiver Flags

Now we come back to quiver flags. Let k be a field. We can consider $\mathrm{Rep}_Q(\underline{d})$ as an affine scheme over k with the obvious functor of points. More generally, we work in the category of schemes over k. Fix a filtration $\underline{\boldsymbol{d}} = (\underline{d}^0 = 0 \leq \underline{d}^1 \leq \cdots \leq \underline{d}^\nu)$.

Denote by $A_{\nu+1}$ the quiver having $\nu + 1$ vertices numbered from 0 to ν and arrows going from vertex i to vertex $i + 1$ for $0 \leq i < \nu$. Let $\Lambda := (kQ)A_{\nu+1}$. Then

$\operatorname{mod}\Lambda$ is the category of sequences of k-representations of Q of length $\nu+1$ and chain maps between them, i.e. a morphism between two modules

$$\boldsymbol{M} = M^0 \to M^1 \to \cdots \to M^\nu$$

and

$$\boldsymbol{N} = N^0 \to N^1 \to \cdots \to N^\nu$$

is given by a commutative diagram

$$\begin{tikzcd}
M^0 \arrow[r] \arrow[d] & M^1 \arrow[r] \arrow[d] & \cdots \arrow[r] & M^\nu \arrow[d] \\
N^0 \arrow[r] & N^1 \arrow[r] & \cdots \arrow[r] & N^\nu.
\end{tikzcd}$$

For Λ it is easy to calculate the Euler form of two modules $\boldsymbol{M}, \boldsymbol{N} \in \operatorname{mod}\Lambda$ by using theorem 3.3:

$$\langle \boldsymbol{M}, \boldsymbol{N} \rangle_\Lambda = \sum_{i=0}^{r} \left\langle M^i, N^i \right\rangle_{kQ} - \sum_{i=0}^{r-1} \left\langle M^i, N^{i+1} \right\rangle_{kQ}.$$

We show that $\operatorname{Gr}_\Lambda \binom{\boldsymbol{M}}{\underline{\boldsymbol{d}}} \cong \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$, where $\boldsymbol{M} = (M = M = \cdots = M)$, and then use the previous results to calculate the tangent space.

Lemma 4.1. Let $\underline{\boldsymbol{d}}$ be a filtration and $M \in \operatorname{Rep}_Q(\underline{d}^\nu)(k)$. Let

$$\boldsymbol{U} = (U^0, U^1, \ldots, U^\nu) \in \operatorname{Fl}_Q \begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} (K)$$

for a field extension K of k. Then we have that

$$T_{\boldsymbol{U}} \operatorname{Fl}_Q \begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} \cong \operatorname{Hom}_{\Lambda\otimes K}(\boldsymbol{U}, (\boldsymbol{M} \otimes K)/\boldsymbol{U}),$$

where $\Lambda = (kQ)A_{\nu+1}$ and $\boldsymbol{M} = (M = M = \cdots = M) \in \operatorname{Mod}_\Lambda(\underline{d}^\nu, \underline{d}^\nu, \ldots, \underline{d}^\nu)(k)$.

Proof. For a submodule

$$\boldsymbol{U} = (U^0 \to U^1 \to \cdots \to U^\nu) \in \operatorname{Gr}_\Lambda \begin{pmatrix} \boldsymbol{M} \\ \underline{\boldsymbol{d}} \end{pmatrix} (R)$$

we have automatically that the maps $U^i \to U^{i+1}$ are injections. Therefore, such a submodule $\boldsymbol{U}$ gives, in a natural way, rise to a flag $\boldsymbol{U} \in \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}(R)$ and vice versa. This yields an isomorphism $\operatorname{Gr}_\Lambda \binom{\boldsymbol{M}}{\underline{\boldsymbol{d}}} \cong \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$. Since $\operatorname{Gr}_\Lambda \binom{\boldsymbol{M}}{\underline{\boldsymbol{d}}}$ is open in $\operatorname{Gr}_\Lambda \binom{\boldsymbol{M}}{d}$, where $d = \sum_{k,i} d_i^k$, we have that, for a point $\boldsymbol{U} \in \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}(K)$,

$$T_{\boldsymbol{U}} \operatorname{Fl}_Q \begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} \cong T_{\boldsymbol{U}} \operatorname{Gr}_\Lambda \begin{pmatrix} \boldsymbol{M} \\ \underline{\boldsymbol{d}} \end{pmatrix} = T_{\boldsymbol{U}} \operatorname{Gr}_\Lambda \begin{pmatrix} \boldsymbol{M} \\ d \end{pmatrix} = \operatorname{Hom}_{\Lambda\otimes K}(\boldsymbol{U}, (\boldsymbol{M} \otimes K)/\boldsymbol{U}).$$

□

We define the closed subscheme $\operatorname{RepFl}_Q(\underline{\boldsymbol{d}})$ of $\operatorname{Rep}_Q(\underline{d}^\nu) \times \operatorname{Fl}(\underline{\boldsymbol{d}})$ by its functor of points

$$\operatorname{RepFl}_Q(\underline{\boldsymbol{d}})(R) := \left\{ (M, \boldsymbol{U}) \in \operatorname{Rep}_Q(\underline{d}^\nu)(R) \times \operatorname{Fl}(\underline{\boldsymbol{d}})(R) \;\middle|\; \boldsymbol{U} \in \operatorname{Fl}_Q \begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} \right\}.$$

We have the following.

Lemma 4.2. Let $\underline{\boldsymbol{d}}$ be a filtration. Consider the two natural projections from the fibre product restricted to $\operatorname{RepFl}_Q(\underline{\boldsymbol{d}})$.

$$\begin{tikzcd}
\operatorname{RepFl}_Q(\underline{\boldsymbol{d}}) \arrow[r, "\pi_1"] \arrow[d, "\pi_2"'] & \operatorname{Rep}_Q(\underline{d}^\nu) \\
\operatorname{Fl}(\underline{\boldsymbol{d}}) &
\end{tikzcd}$$

Then π_1 is projective and π_2 is a vector bundle of rank

$$\sum_{k=1}^{\nu} \sum_{\alpha: i \to j} d_j^k (d_i^k - d_i^{k-1}).$$

Therefore, $\operatorname{RepFl}_Q(\underline{\boldsymbol{d}})$ is smooth and irreducible of dimension

$$\sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^{k+1} - \underline{d}^k \right\rangle_Q + \dim \operatorname{Rep}_Q(\underline{d}^\nu).$$

Finally, the (scheme-theoretic) image $\mathcal{A}_{\underline{\boldsymbol{d}}} := \pi_1(\operatorname{RepFl}_Q(\underline{\boldsymbol{d}}))$ is a closed, irreducible subvariety of $\operatorname{Rep}_Q(\underline{d}^\nu)$.

Proof. π_1 is projective since it factors as a closed immersion into projective space times Rep_Q followed by the projection to Rep_Q.

For $\underline{I} = (I_i)_{i \in Q_0}$, each $I_i \subset \{1, \ldots, d_i^\nu\}$, we set $W_{\underline{I}}$ to be the graded subspace of $k^{\underline{d}^\nu}$ with basis $\{e_j\}_{j \in I_i}$ in the i-th graded part $k^{d_i^\nu}$ and $|\underline{I}| := (|I_i|)_{i \in Q_0} \in \mathbb{N}^{Q_0}$. For a sequence $\underline{\boldsymbol{I}} = (\underline{I}^0, \underline{I}^1, \ldots, \underline{I}^\nu)$ such that $I_i^k \supset I_i^{k+1}$ and $|\underline{I}^k| = \underline{d}^\nu - \underline{d}^k$ we set

$$\boldsymbol{W}_{\underline{\boldsymbol{I}}} := (W_{\underline{I}^0}, \ldots, W_{\underline{I}^\nu})$$

to be the decreasing sequence of subspaces associated to $\underline{\boldsymbol{I}}$. We show that π_2 is trivial over the open affine subset $U_{\underline{\boldsymbol{I}}}$ of $\operatorname{Fl}(\underline{\boldsymbol{d}})$ given by

$$U_{\underline{\boldsymbol{I}}}(R) := \left\{ \boldsymbol{U} \in \operatorname{Fl}(\underline{\boldsymbol{d}})(R) \;\middle|\; U^k \oplus (W_{\underline{I}^k} \otimes R) = R^{\underline{d}^\nu} \right\}.$$

Without loss of generality we assume $I_i^k = \{d_i^k + 1, \ldots, d_i^\nu\}$. Each element $\boldsymbol{U} \in U_{\underline{\boldsymbol{I}}}(R)$ is given uniquely by some matrices $A_i^k \in \operatorname{Mat}_{(d_i^\nu - d_i^k) \times (d_i^k - d_{i-1}^k)}$ such that

$$U_i^k = \operatorname{Im} \begin{pmatrix} \mathrm{id}_{d_i^1} & 0 & \cdots & 0 \\ & \mathrm{id}_{d_i^2 - d_i^1} & \ddots & \vdots \\ \boxed{A_i^1} & & \ddots & 0 \\ & \boxed{A_i^2} & \ddots & \mathrm{id}_{d_i^k - d_i^{k-1}} \\ & & \cdots & \boxed{A_i^k} \end{pmatrix}.$$

Let $V^k := W_{(\{1, \ldots, d_i^k\})}$. Let X be the closed subscheme of $\operatorname{Rep}_Q(\underline{d}^\nu)$ given by the functor of points

$$X(R) := \left\{ M \in \operatorname{Rep}_Q(\underline{d}^\nu) \;\middle|\; V^k \otimes R \text{ is a subrepresentation of } M \;\forall\, 0 \le k \le \nu \right\}.$$

Note that X is an affine space of dimension

$$\sum_{k=1}^{\nu}\sum_{\alpha:i\to j} d_j^k(d_i^k-d_i^{k-1}).$$

Let $g_{\boldsymbol{U}} := (g_i)_{i\in Q_0}$ where

$$g_i = \begin{pmatrix} \mathrm{id}_{d_i^1} & 0 & \cdots & 0 & 0 \\ & \mathrm{id}_{d_i^2-d_i^1} & \ddots & \vdots & 0 \\ \boxed{A_i^1} & & \ddots & 0 & \vdots \\ & \boxed{A_i^2} & \ddots & \mathrm{id}_{d_i^{\nu-1}-d_i^{\nu-2}} & 0 \\ & & \cdots & \boxed{A_i^{\nu-1}} & \mathrm{id}_{d_i^{\nu}-d_i^{\nu-1}} \end{pmatrix} \in \mathrm{GL}_{d_i^{\nu}}(k).$$

Then, the map from $X\times U_{\underline{\boldsymbol{I}}}$ to $U_{\underline{\boldsymbol{I}}}\times_{\mathrm{Fl}}\mathrm{RepFl}_Q(\underline{\boldsymbol{d}})$ given by sending $(M,\boldsymbol{U})$ to $(g_{\boldsymbol{U}}\cdot M,\boldsymbol{U})$ is an isomorphism which induces an isomorphism of vector spaces on the fibres. Therefore, we have that π_2 is a vector bundle.

Finally, we prove the claim on dimension. Since $\mathrm{Fl}(\underline{\boldsymbol{d}})$ is smooth, we have that

$$\begin{aligned}\dim\mathrm{Fl}(\underline{\boldsymbol{d}}) &= \sum_{i\in Q_0}\sum_{k=1}^{\nu-1}\sum_{l=k+1}^{\nu}(d_i^k-d_i^{k-1})(d_i^l-d_i^{l-1}) \\ &= \sum_{i\in Q_0}\left(\sum_{k=1}^{\nu-1}\sum_{l=k+1}^{\nu} d_i^k(d_i^l-d_i^{l-1}) - \sum_{k=1}^{\nu-2}\sum_{l=k+2}^{\nu} d_i^k(d_i^l-d_i^{l-1})\right) \\ &= \sum_{i\in Q_0}\left(d^{\nu-1}(d_i^{\nu}-d_i^{\nu-1})+\sum_{k=1}^{\nu-2}d_i^k(d_i^{k+1}-d_i^k)\right) = \sum_{i\in Q_0}\left(\sum_{k=1}^{\nu-1}d_i^k(d_i^{k+1}-d_i^k)\right).\end{aligned}$$

Since $\mathrm{RepFl}_Q(\underline{\boldsymbol{d}})$ is smooth and π_2 is a vector bundle we obtain

$$\begin{aligned}\dim\mathrm{RepFl}_Q(\underline{\boldsymbol{d}}) &= \dim\mathrm{Fl}(\underline{\boldsymbol{d}}) + \sum_{\alpha\colon i\to j}\sum_{k=1}^{\nu}(d_i^k-d_i^{k-1})d_j^k \\ &= \sum_{i\in Q_0}\left(\sum_{k=1}^{\nu-1}d_i^k(d_i^{k+1}-d_i^k)\right) + \sum_{\alpha\colon i\to j}\sum_{k=1}^{\nu}(d_i^k-d_i^{k-1})d_j^k \\ &= \sum_{k=1}^{\nu-1}\left(\sum_{i\in Q_0}d_i^k(d_i^{k+1}-d_i^k) + \sum_{\alpha\colon i\to j}d_i^k(d_j^k-d_j^{k+1})\right) + \sum_{\alpha\colon i\to j}d_i^{\nu}d_j^{\nu} \\ &= \sum_{k=1}^{\nu-1}\left\langle \underline{d}^k, \underline{d}^{k+1}-\underline{d}^k\right\rangle_Q + \dim\mathrm{Rep}_Q(\underline{d}^{\nu}).\end{aligned}$$

□

Remark 4.3. Note that if M is a k-valued point of $\mathcal{A}_{\underline{\boldsymbol{d}}}$ for k not algebraically closed, then M does not necessarily have a flag of type $\underline{\boldsymbol{d}}$. This only becomes true after a finite field extension.

We now can give an estimate for the codimension of $\mathcal{A}_{\underline{\boldsymbol{d}}}$ in $\operatorname{Rep}_Q(\underline{d}^\nu)$. For this we use Chevalley's theorem.

Theorem 4.4 (Chevalley). Let k be a field, X, Y irreducible k-schemes and $f\colon X \to Y$ a dominant morphism. Then for every point $y \in Y$ and every point $x \in f^{-1}(y)$, the scheme theoretic fibre, we have that

$$\dim_x f^{-1}(y) \geq \dim X - \dim Y.$$

Moreover, on an open, non-empty subset of X we have equality.

Proof. See [Gro65, §5, Proposition 5.6.5]. ☐

Theorem 4.5. Let $\underline{\boldsymbol{d}}$ be a filtration, K a field extension of k, $\Lambda := (KQ)A_{\nu+1}$ and $(M, \boldsymbol{U}) \in \operatorname{RepFl}_Q(\underline{\boldsymbol{d}})(K)$. Let $\boldsymbol{M} = (M = \cdots = M)$ as a Λ-module. Then we have that

$$\operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{d}}} \leq \dim \operatorname{Ext}^1_\Lambda(\boldsymbol{U}, \boldsymbol{M}/\boldsymbol{U}) \leq \dim \operatorname{Ext}^1_\Lambda(\boldsymbol{U}, \boldsymbol{M}) \leq \dim \operatorname{Ext}^1_{KQ}(M, M).$$

Proof. Since $\dim \mathcal{A}_{\underline{\boldsymbol{d}}}$ is stable under flat base change we can assume $k = K$. Let $\boldsymbol{V} := \boldsymbol{M}/\boldsymbol{U}$. Then we have the following short exact sequence of Λ-modules:

$$\begin{tikzcd}
0: \arrow[d] & 0 \arrow[r] \arrow[d] & 0 \arrow[r] \arrow[d] & \cdots \arrow[r] & 0 \arrow[d] \\
\boldsymbol{U}: \arrow[d] & U^0 \arrow[r] \arrow[d] & U^1 \arrow[r] \arrow[d] & \cdots \arrow[r] & U^\nu \arrow[d] \\
\boldsymbol{M}: \arrow[d] & M \arrow[r, equal] \arrow[d] & M \arrow[r, equal] \arrow[d] & \cdots \arrow[r, equal] & M \arrow[d] \\
\boldsymbol{V}: \arrow[d] & V^0 \arrow[r] \arrow[d] & V^1 \arrow[r] \arrow[d] & \cdots \arrow[r] & V^\nu \arrow[d] \\
0: & 0 \arrow[r] & 0 \arrow[r] & \cdots \arrow[r] & 0.
\end{tikzcd}$$

We already know that $\operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V})$ is the tangent space of $\operatorname{Fl}\binom{M}{\underline{\boldsymbol{d}}}$ at the point $\boldsymbol{U}$. Using Chevalley's theorem, we have that

$$\dim \operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V}) \geq \dim_{\boldsymbol{U}} \operatorname{Fl}\binom{M}{\underline{\boldsymbol{d}}} \geq \dim \operatorname{RepFl}_Q(\underline{\boldsymbol{d}}) - \dim \mathcal{A}_{\underline{\boldsymbol{d}}}$$

and therefore

$$\dim \mathcal{A}_{\underline{\boldsymbol{d}}} \geq \dim \operatorname{RepFl}_Q(\underline{\boldsymbol{d}}) - \dim \operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V}).$$

We now calculate

$$\begin{aligned}
\langle \boldsymbol{U}, \boldsymbol{V} \rangle_\Lambda &= \sum_{k=0}^{\nu} \left\langle U^k, V^k \right\rangle_Q - \sum_{k=0}^{\nu-1} \left\langle U^k, V^{k+1} \right\rangle_Q \\
&= \sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^\nu - \underline{d}^k \right\rangle_Q - \sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^\nu - \underline{d}^{k+1} \right\rangle_Q = \sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^{k+1} - \underline{d}^k \right\rangle_Q .
\end{aligned}$$

Recall that

$$\dim \operatorname{RepFl}_Q(\underline{\boldsymbol{d}}) = \sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^{k+1} - \underline{d}^k \right\rangle_Q + \dim \operatorname{Rep}_Q(\underline{d}^\nu).$$

In total

$$\begin{aligned} &\operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{d}}} \leq \dim \operatorname{Rep}(\underline{d}) + \dim \operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V}) - \dim \operatorname{RepFl}_Q(\underline{\boldsymbol{d}}) \\ &= \dim \operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V}) - \sum_{k=1}^{\nu-1} \left\langle \underline{d}^k, \underline{d}^{k+1} - \underline{d}^k \right\rangle_Q = \dim \operatorname{Hom}_\Lambda(\boldsymbol{U}, \boldsymbol{V}) - \langle \boldsymbol{U}, \boldsymbol{V} \rangle_\Lambda \\ &\qquad = \dim \operatorname{Ext}^1_\Lambda(\boldsymbol{U}, \boldsymbol{V}) - \dim \operatorname{Ext}^2_\Lambda(\boldsymbol{U}, \boldsymbol{V}). \end{aligned}$$

Here we have the last equality since $\operatorname{gldim} \Lambda \leq 2$. Since $\operatorname{gldim} kQ = 1$ and $P = P = \cdots = P$ is projective in $\operatorname{mod} \Lambda$ for every projective P in $\operatorname{mod} kQ$ we see that $\operatorname{pd}_\Lambda \boldsymbol{M} \leq 1$ and similarly $\operatorname{id}_\Lambda \boldsymbol{M} \leq 1$. Consider, as before, the short exact sequence

$$0 \to \boldsymbol{U} \to \boldsymbol{M} \to \boldsymbol{V} \to 0.$$

Since $\boldsymbol{M}$ has projective dimension less than two we have that $(\boldsymbol{U}, \boldsymbol{U})^2 = 0$ and that $(\boldsymbol{U}, \boldsymbol{V})^2 = 0$. Applying $(-, \boldsymbol{M})$ gives a surjection $(\boldsymbol{M}, \boldsymbol{M})^1 \to (\boldsymbol{U}, \boldsymbol{M})^1$. Applying $(\boldsymbol{U}, -)$ yields a surjection $(\boldsymbol{U}, \boldsymbol{M})^1 \to (\boldsymbol{U}, \boldsymbol{V})^1$. Hence the above result simplifies to

$$\operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{a}}} \leq \dim \operatorname{Ext}^1(\boldsymbol{U}, \boldsymbol{V}) \leq \dim \operatorname{Ext}^1(\boldsymbol{U}, \boldsymbol{M}) \leq \dim \operatorname{Ext}^1(\boldsymbol{M}, \boldsymbol{M}).$$

Obviously, $\operatorname{Ext}^1_\Lambda(\boldsymbol{M}, \boldsymbol{M}) \cong \operatorname{Ext}^1_{kQ}(M, M)$ and the claim follows. □

Remark 4.6. Note that if the characteristic of k is 0, then, by generic smoothness, there is a point $M \in \mathcal{A}_{\underline{\boldsymbol{d}}}$ and an $\boldsymbol{U} \in \operatorname{Fl}\binom{M}{\underline{\boldsymbol{d}}}$ such that $\operatorname{Fl}\binom{M}{\underline{\boldsymbol{d}}}$ is smooth in $\boldsymbol{U}$ and the value of $\dim \operatorname{Ext}^1_{\Lambda \otimes K}(\boldsymbol{U}, (M \otimes K)/\boldsymbol{U})$ is minimal. In this case we have that

$$\operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{d}}} = \dim \operatorname{Ext}^1_{\Lambda \otimes K}(\boldsymbol{U}, (M \otimes K)/\boldsymbol{U}).$$

We also construct an additional vector bundle.

Definition 4.7. Let $\underline{\boldsymbol{d}}$ be a filtration. Let $\operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})$ be the scheme given via its functor of points

$$\begin{aligned} &\operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(R) := \\ &\left\{ (\boldsymbol{U}, \boldsymbol{f}) \in \prod_{i=0}^{\nu} \operatorname{Rep}_Q(\underline{d}^i)(R) \times \prod_{i=0}^{\nu-1} \operatorname{Hom}(\underline{d}^i, \underline{d}^{i+1})(R) \;\middle|\; f^i \in \operatorname{Hom}_{RQ}(U^i, U^{i+1}) \right\}. \end{aligned}$$

Let $\operatorname{IRep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})$ be the open subscheme of $\operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})$ given by its functor of points

$$\operatorname{IRep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(R) := \left\{ (\boldsymbol{U}, \boldsymbol{f}) \in \operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(R) \;\middle|\; f^i \in \operatorname{Inj}(\underline{d}^i, \underline{d}^{i+1})(R) \right\}.$$

Remark 4.8. Note that $\operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(k)$ consists of sequences of k-representations of Q. Therefore, these are modules over $(kQ)A_{\nu+1}$. Vice versa, every $(kQ)A_{\nu+1}$-module of dimension vector $\underline{\boldsymbol{d}}$ is isomorphic to an element of $\operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(k)$.

We will often write $\boldsymbol{U}$ instead of $(\boldsymbol{U}, \boldsymbol{f})$ for an $(\boldsymbol{U}, \boldsymbol{f}) \in \operatorname{Rep}_{Q, A_{\nu+1}}(\underline{\boldsymbol{d}})(R)$.

Lemma 4.9. Let $\underline{\boldsymbol{d}}$ be a filtration. Then the projection

$$\pi\colon \quad \mathrm{IRep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}) \to \prod_{i=0}^{\nu-1} \mathrm{Inj}(\underline{d}^i, \underline{d}^{i+1})$$

given by sending

$$(\boldsymbol{U}, \boldsymbol{f}) \mapsto \boldsymbol{f}$$

is a vector bundle and therefore flat. In particular, $\mathrm{IRep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})$ is smooth and irreducible.

Proof. The first part is analogously to lemma 4.2. Irreducibility then follows by the fact that flat morphisms are open and proposition 1.6. ☐

Before we continue, we give the following easy lemma, stated by K. Bongartz in [Bon94], which gives rise to a whole class of vector bundles.

Lemma 4.10. Let X be a variety over a ground ring k. Let $m, n \in \mathbb{N}$ and $f\colon X \to \mathrm{Hom}(m,n)_k$ a morphism. Then for any $r \in \mathbb{N}$, the variety $X(r)$ given by the functor of points

$$X(r)(R) := \{\, x \in X(R) \mid f(x) \in \mathrm{Hom}(m,n)_{m-r}(R) \,\}$$

is a locally closed subvariety of X. Moreover, the closed subvariety

$$U_r(R) := \{\, (x,v) \in X(r)(R) \times R^m \mid f(x)(v) = 0 \,\}$$

of $X(r) \times k^m$ is a sub vector bundle of rank r over $X(r)$.

Proof. The claim follows easily by using Fitting ideals. ☐

Example 4.11. Let $(\boldsymbol{M}, \boldsymbol{g}) \in \mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{e}})(k)$.

Let $\varphi\colon \mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}) \to \mathrm{Hom}(m,n)$ be the morphism given by

$$(\boldsymbol{U}, \boldsymbol{f}) \mapsto \left(\boldsymbol{h} = (h_i^k) \mapsto \left((h_j^k U_\alpha^k - M_\alpha^k h_i^k)_{\substack{\alpha\colon i\to j,\\ 0\le k\le\nu}}, (h_i^{k+1} f_i^k - g_i^k h_i^k)_{\substack{i\in Q_0\\ 0\le k\le\nu}} \right) \right)$$

for every $(\boldsymbol{U}, \boldsymbol{f}) \in \mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(R)$, where

$$m = \sum_{i\in Q_0} \sum_{k=0}^{\nu} d_i^k e_i^k \qquad \text{and} \qquad n = \sum_{k=0}^{\nu} \sum_{\alpha\colon i\to j} d_i^k e_j^k + \sum_{k=0}^{\nu-1} \sum_{i\in Q_0} d_i^k e_i^{k+1}.$$

Then $\boldsymbol{h} \in \ker \varphi(\boldsymbol{U}, \boldsymbol{f})$ if and only if $\boldsymbol{h} \in \mathrm{Hom}_{(RQ)A_{\nu+1}}(\boldsymbol{U}, \boldsymbol{M} \otimes R)$.

Set

$$\mathrm{RepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r := U_r(R)$$

from the previous lemma. Note that elements $(\boldsymbol{U}, \boldsymbol{h}) \in \mathrm{RepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r(R)$ are all pairs consisting of a representation $\boldsymbol{U} \in \mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(R)$ and a morphism $\boldsymbol{h} \in \mathrm{Hom}_{(RQ)A_{\nu+1}}(\boldsymbol{U}, \boldsymbol{M})$ such that $\operatorname{rank} \mathrm{Hom}_{(RQ)A_{\nu+1}}(\boldsymbol{U}, \boldsymbol{M}) = r$.

The lemma yields that the projection

$$\mathrm{RepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r \to \mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(r)$$
$$(\boldsymbol{U}, \boldsymbol{h}) \mapsto \boldsymbol{U}$$

is a vector bundle of rank r.

It also stays a vector bundle if we restrict it to the open subset $\mathrm{IRep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(r)$ of $\mathrm{Rep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(r)$. We denote the preimage under the projection to this variety by $\mathrm{IRepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r$.

We obtain the following.

Theorem 4.12. Let $\underline{\boldsymbol{d}}$ be a filtration and K a field extension of k. Assume that there is an $M \in \mathcal{A}_{\underline{\boldsymbol{d}}}(K)$ such that $\dim \operatorname{Ext}^1_{KQ}(M,M) = \operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{d}}}$. Then $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ is smooth over K and geometrically irreducible.

Proof. Smoothness is an immediate consequence of the last theorem, since we have that $\dim T_{\boldsymbol{U}} \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ is constant and smaller or equal to the dimension at each irreducible component living in $\boldsymbol{U}$. Since K is a field this implies smoothness. See [DG70, I, §4, no 4].

Now we prove irreducibility. By base change we can assume that K is algebraically closed. Consider all the following schemes as K-varieties. We construct the following diagram of varieties.

$$\begin{tikzcd}
 & \operatorname{IRepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}},\boldsymbol{M})_r \arrow[d, two heads, "\text{vector bundle}"] & \operatorname{IRepInj}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}},\boldsymbol{M})_r \arrow[l, hook', "\text{open}"'] \arrow[d, two heads] \\
\operatorname{IRep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}) & \operatorname{IRep}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}})(r) \arrow[l, hook', "\text{open}"'] & \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}},
\end{tikzcd}$$

r being equal to $\langle \underline{\boldsymbol{d}}, \boldsymbol{M} \rangle_\Lambda + [M,M]^1$. Since open subvarieties and images of irreducible varieties are again irreducible and by application of proposition 1.6 we then obtain that $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ also is irreducible.

Consider the minimal value r of $\dim \operatorname{Hom}(\boldsymbol{U}, \boldsymbol{M})$ for $\boldsymbol{U} \in \operatorname{IRep}(\underline{\boldsymbol{d}})(K)$. Denote by

$$\begin{aligned} \pi \colon \operatorname{IRep}(\underline{\boldsymbol{d}}) &\to \operatorname{Rep}_Q(\underline{d}^\nu) \\ \boldsymbol{U} &\mapsto U^\nu. \end{aligned}$$

Since $\mathcal{O}_M$ is open in $\mathcal{A}_{\underline{\boldsymbol{d}}}$ and IRep is irreducible, the intersection of the two open sets $\pi^{-1}(\mathcal{O}_M)$ and $\operatorname{IRep}(r)$ is non-empty. For all elements $\boldsymbol{U}$ of $\pi^{-1}(\mathcal{O}_M)$ we have, by theorem 4.5, that $[\boldsymbol{U}, \boldsymbol{M}]^1_\Lambda = [M,M]^1_Q$. We already saw that $[\boldsymbol{U}, \boldsymbol{M}]^2 = 0$, therefore

$$[\boldsymbol{U}, \boldsymbol{M}]_\Lambda = \langle \boldsymbol{U}, \boldsymbol{M} \rangle_\Lambda + [\boldsymbol{U}, \boldsymbol{M}]^1_\Lambda = \langle \underline{\boldsymbol{d}}, \boldsymbol{M} \rangle_\Lambda + [M,M]^1_Q.$$

This means that the dimension of the homomorphism space is constant on $\pi^{-1}(\mathcal{O}_M)$ and we obtain that $r = \langle \underline{\boldsymbol{d}}, \boldsymbol{M} \rangle_\Lambda + [M,M]^1_Q$. Moreover, IRep_r is irreducible as an open subset of IRep.

We then have that $\operatorname{IRepHom}_{Q,A_{\nu+1}}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r$ is irreducible, since it is a vector bundle on IRep_r by example 4.11. Take the open subvariety $\operatorname{IRepInj}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r$ of $\operatorname{IRepHom}(\underline{\boldsymbol{d}}, \boldsymbol{M})_r$ where the morphism to $\boldsymbol{M}$ is injective. It is irreducible as an open subset of an irreducible variety. The projection from this variety to $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ is surjective since $\pi^{-1}(\mathcal{O}_M)$ is contained in $\operatorname{IRep}(\underline{\boldsymbol{d}})(r)$, and therefore $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}}$ is irreducible. □

We now want to interpret theorem 4.12 in terms of Hall numbers. Let X_0 be a variety defined over a finite field $\mathbb{F}_q$, where $q = p^n$ for a prime n. Denote by $\overline{\mathbb{F}_q}$ the algebraic closure of $\mathbb{F}_q$ and by $X := X_0 \otimes \overline{\mathbb{F}_q}$ the variety obtained from X_0 by base change from $\mathbb{F}_q$ to $\overline{\mathbb{F}_q}$. Let F be the Frobenius automorphism acting on X. Denote by $H^i(X, \mathbb{Q}_\ell)$ the ℓ-adic cohomology group with compact support for a prime $\ell \neq p$, see for example [FK88]. Denote by F^i the induced action of F on cohomology $H^i(X, \mathbb{Q}_\ell)$. P. Deligne proved the following theorem.

Theorem 4.13 (P. Deligne [Del80], 3.3.9). Let X_0 be a proper and smooth variety over $\mathbb{F}_q$. For every i, the characteristic polynomial $\det(T \operatorname{id} - F^i, H^i(X, \mathbb{Q}_\ell))$ is a polynomial with coefficients in $\mathbb{Z}$, independent of ℓ ($\ell \neq p$). The complex roots α of this polynomial have absolute value $|\alpha| = q^{\frac{i}{2}}$.

Moreover, the Lefschetz fixed point formula yields that

$$\#X_0(\mathbb{F}_{q^n}) = \sum_{i \geq 0} (-1)^i \operatorname{Tr}((F^i)^n, H^i(X, \mathbb{Q}_\ell)).$$

Assume now that there is a polynomial $P \in \mathbb{Q}[t]$ such that, for each finite field extension $L/\mathbb{F}_q$ we have that $\#X_0(L) = P(|L|)$, $|L|$ being the number of elements of the finite field. We call P the counting polynomial of X_0. Then we have the following.

Theorem 4.14. Let X_0 be proper and smooth over $\mathbb{F}_q$ with counting polynomial P. Then odd cohomology of X vanishes and

$$P(t) = \sum_{i=0}^{\dim X_0} \dim H^{2i}(X, \mathbb{Q}_\ell) t^i.$$

Proof. See [CBVdB04, Lemma A.1]. □

Assume now that Y is a projective scheme over $\mathbb{Z}$ and set $Y_k := Y \otimes k$ for any field k. Note that for Y ℓ-adic cohomology agrees with ℓ-adic cohomology with compact support. Assume furthermore that there is a counting polynomial $P \in \mathbb{Q}[t]$ such that, for each finite field k, we have that $\#Y_k(k) = P(|k|)$. By the base change theorem [FK88, Theorem 1.6.1] we have

$$H^i(Y_{\overline{\mathbb{Q}}}, \mathbb{Q}_\ell) \cong H^i(Y_{\mathbb{C}}, \mathbb{Q}_\ell).$$

By the comparison theorem [FK88, Theorem 1.11.6] we have

$$H^i(Y_{\mathbb{C}}, \mathbb{Q}_\ell) \cong H^i(Y_{\mathbb{C}}(\mathbb{C}), \mathbb{Q}_\ell),$$

where on the right hand side we consider the usual cohomology of the complex analytic manifold attached to $Y_{\mathbb{C}}$.

Moreover, there is an open, dense subset U of $\operatorname{Spec} \mathbb{Z}$ such that $H^i(Y_{\overline{\kappa(v)}}, \mathbb{Q}_\ell) \cong H^i(Y_{\overline{\mathbb{Q}}}, \mathbb{Q}_\ell)$ for all $v \in U$, where $\kappa(v)$ denotes the residue field at v. This means that for almost all primes p we have that

$$H^i(Y_{\overline{\mathbb{F}_p}}, \mathbb{Q}_\ell) \cong H^i(Y_{\overline{\mathbb{Q}}}, \mathbb{Q}_\ell) \cong H^i(Y_{\mathbb{C}}(\mathbb{C}), \mathbb{Q}_\ell).$$

Therefore, if we know the Betti numbers of $Y_{\mathbb{C}}(\mathbb{C})$, then we know the coefficients of the counting polynomial. In order to apply this to our situation we use the following theorem of W. Crawley-Boevey [CB96b].

Theorem 4.15. Let M be an k-representation without self-extensions. Then there is a $\mathbb{Z}$-representation N such that $M = N \otimes k$ and for all fields K we have that $\operatorname{Ext}(N \otimes K, N \otimes K) = 0$.

Putting all this together, we obtain the following.

Theorem 4.16. Assume that there is an $M \in \mathcal{A}_{\underline{\boldsymbol{d}}}(\mathbb{Q})$, being a direct sum of exceptional representations, such that

$$\dim \operatorname{Ext}^1_{\mathbb{Q}Q}(M,M) = \operatorname{codim} \mathcal{A}_{\underline{\boldsymbol{d}}}.$$

Let N be a $\mathbb{Z}$-representation and $P \in \mathbb{Q}[t]$ a polynomial, such that $N \otimes \mathbb{Q} \cong M$ and $\#\operatorname{Fl}_Q\binom{N\otimes\mathbb{F}_q}{\underline{\boldsymbol{d}}} = P(q)$ for every prime power q. Then $P(0) = 1$ and $P(1) = \chi\left(\operatorname{Fl}_Q\binom{M\otimes\mathbb{C}}{\underline{\boldsymbol{d}}}\right) > 0$.

Moreover, if Q is Dynkin or extended Dynkin, then there is a representation N and a polynomial P with the required properties.

Proof. Let $X := \operatorname{Fl}_Q\binom{N}{\underline{\boldsymbol{d}}}$ as a scheme over $\mathbb{Z}$. Using theorem 4.12 we obtain that X_k is smooth and irreducible for every field k. By the previous discussion we have then that the i-th coefficient of P is exactly $\dim H^{2i}(X_{\mathbb{C}}(\mathbb{C}), \mathbb{Q}_\ell)$ and that odd cohomology vanishes. Therefore,

$$0 < \sum \dim H^{2i}(X_{\mathbb{C}}(\mathbb{C}), \mathbb{Q}_\ell) = \chi\left(X_{\mathbb{C}}\right) = P(1).$$

By irreducibility we have that

$$P(0) = \dim H^0(X_{\mathbb{C}}(\mathbb{C}), \mathbb{Q}_\ell) = 1$$

and this proves the first claims.

If Q is Dynkin or extended Dynkin, then let N be the $\mathbb{Z}$-representation given by theorem 4.15. We have the polynomial P since we have Hall polynomials in both cases for exceptional representations by results of Ringel [Rin90b] and Hubery [Hub07]. □

Let q be a prime power and M an $\mathbb{F}_q$-representation of a Dynkin quiver Q. If $\overline{\mathcal{O}_M} = \mathcal{A}_w$ for some word w in simples, then $F^M_w = 1 \mod q$. Therefore, in the Dynkin case, the generic coefficient in the expression u_w in the Hall algebra is equal to one modulo q. In section 6 we will show that even more is true, namely that every non-zero coefficient in this expression is equal to one modulo q.

5. A geometric version of BGP reflection functors

In this chapter we want to define a geometric version of BGP reflection functors. First we recall the definition of the usual BGP reflection functors as introduced by Bernšteĭn, Gel′fand and Ponomarev [BGP73]. Then we go on to define reflection functors on flags of subrepresentations. In the remainder of this paper we fix a field k and consider only k-valued points of all varieties, if not otherwise stated.

Now we recall the definition of BGP reflection functors. The main reference for this section is [Rin84]. For a nice introduction see [Kra07].

Let Q be a quiver and $\underline{d}$ be a dimension vector. For each vertex $a \in Q_0$ we have the reflection

$$\begin{aligned} \sigma_a\colon \quad \mathbb{Z}Q_0 &\to \mathbb{Z}Q_0 \\ \underline{d} &\mapsto \underline{d} - \left(\underline{d}\,, \epsilon_a\right)_Q \epsilon_a. \end{aligned}$$

If Q has no loop at a, one easily checks that $\sigma_a^2\underline{d} = \underline{d}$.

We also define reflections on the quiver itself. The quiver $\sigma_a Q$ is obtained from Q by reversing all arrows ending or starting in a. If $\alpha\colon a \to j$ is an arrow in Q_1, then we call $\alpha^* : j \to a$ the arrow in the other direction and analogously for $\alpha\colon i \to a$. We have that $(\sigma_a Q)_0 = Q_0$, therefore we can regard $\sigma_a\underline{d}$ as a dimension vector on

$\sigma_a Q$. Obviously, $\sigma_a^2 Q = Q$ if we identify α^{**} with α (and we will do this in the remainder).

If a is a sink of Q, we define for each k-representation M of Q the homomorphism

$$\phi_a^M \colon \bigoplus_{\alpha : j \to a} M_j \xrightarrow{(\,M_\alpha\,)} M_a.$$

Dually, if b is a source of Q, we define

$$\phi_b^M \colon M_b \xrightarrow{(\,M_\alpha\,)} \bigoplus_{\alpha : b \to j} M_j.$$

Note that $D\phi_a^{DM} = \phi_a^M$, where D denotes the k-dual, and that $d_a - \operatorname{rank} \phi_a^X = \dim \operatorname{Hom}(X, S_a)$ for a a sink of Q and a representation X of dimension vector $\underline{d}$.

We define a pair of reflection functors S_a^+ and S_b^-. To this end we fix a k-representation M of Q of dimension vector $\underline{d}$. If the vertex a is a sink of Q we construct

$$S_a^+ \colon \operatorname{rep}(Q,k) \to \operatorname{rep}(\sigma_a Q, k)$$

as follows. We define $S_a^+ M := N$ by letting $N_i := M_i$ for a vertex $i \neq a$ and letting N_a be the kernel of the map Φ_a^M. Denote by $\iota\colon \operatorname{Ker} \phi_a^M \to \bigoplus M_j$ the canonical inclusion and by $\pi_i \colon \bigoplus M_j \to M_i$ the canonical projection. Then, for each $\alpha : i \to a$ we let $N_{\alpha^*} \colon \operatorname{Ker} \phi_a^M \to M_i$ be the composition $\pi_i \circ \iota$ making the following diagram commute

$$\begin{tikzcd}
0 \arrow[r] & \operatorname{Ker} \phi_a^M \arrow[r, "\iota"'] \arrow[d, "N_{\alpha^*}"] & \bigoplus M_j \arrow[r] \arrow[d, "\pi_i"] & M_a \\
 & M_i \arrow[r, equal] & M_i.
\end{tikzcd}$$

We obtain a k-representation N of $\sigma_a Q$. We call this representation $S_a^+ M$. This construction yields a functor S_a^+.

Let $s := d_a - \operatorname{rank} \phi_a^M$ be the codimension of $\operatorname{Im} \phi_a^M$ in M_a. We have that

$$e_a := \dim(S_a^+ M)_a = \sum_{\alpha : i \to a} d_i - \operatorname{rank} \Phi_a^M = d_a - (\underline{d}, \epsilon_a) + s = d_a - s - (\underline{d} - s\epsilon_a, \epsilon_a).$$

Therefore, $\underline{\dim}\,(S_a^+ M) = \sigma_a(\underline{d} - s\epsilon_a) = \sigma_a(\underline{d}) + s\epsilon_a$. Dually, for a sink of b of Q we obtain a functor S_b^-.

For a sink a of Q we have that (S_a^-, S_a^+) is a pair of adjoint functors and that S_a^+ is left exact and S_a^- is right exact. There is a natural monomorphism $\iota_{a,M} \colon S_a^- S_a^+ M \to M$ for $M \in \operatorname{rep}(Q,k)$ and a natural epimorphism $\pi_{a,N} \colon N \to S_a^+ S_a^- N$ for $N \in \operatorname{rep}(\sigma_a Q, k)$. We have the following lemma.

Lemma 5.1. Let a be a sink and X an indecomposable k-representation of Q. Then, the following are equivalent:

(1) $X \ncong S_a$.
(2) $S_a^+ X$ is indecomposable.
(3) $S_a^+ X \neq 0$.
(4) $S_a^- S_a^+ X \cong X$ via the natural inclusion.
(5) The map Φ_a^X is an epimorphism.
(6) $\sigma_a(\underline{\dim} X) > 0$.
(7) $\underline{\dim} S_a^+ X = \sigma_a(\underline{\dim} X)$.

An sequence $(i_1,\dots,i_r)$ of the vertices of Q is called admissible, if i_p is a sink in $\sigma_{i_{p-1}}\cdots\sigma_{i_1}Q$ for each $1\le p\le r$. An admissible sequence is called admissible ordering if each vertex of Q appears exactly once in the sequence. Note that there is an admissible ordering if and only if Q has no oriented cycles. Such a quiver is called acyclic. In the following we always assume that Q is acyclic. For any admissible sequence of sinks $w=(i_1,\dots,i_r)$ define

$$S_w^+ := S_{i_r}^+\circ\cdots\circ S_{i_1}^+.$$

If $w=(i_1,\dots,i_n)$ is an admissible ordering of Q, we define the Coxeter functors

$$C^+ := S_{i_n}^+\circ\cdots\circ S_{i_1}^+ \qquad\qquad C^- := S_{i_1}^-\circ\cdots\circ S_{i_n}^-.$$

Since both reverse each arrow of Q exactly twice, these are endofunctors of $\operatorname{rep}(Q,k)$. Neither functor depends on the choice of the admissible ordering.

A k-representation P is projective if and only if $C^+P=0$. Dually, a k-representation I is injective if and only if $C^-I=0$. An indecomposable k-representation M of Q is called preprojective if $(C^+)^rM=0$ for some $r\ge 0$ and preinjective if $(C^-)^rM=0$ for some $r\ge 0$. If M is neither preprojective nor preinjective, then M is called regular.

An arbitrary k-representation is called preprojective (or preinjective or regular) if it is isomorphic to a direct sum of indecomposable preprojective (or preinjective or regular) representations.

Let M be a k-representation of Q and $\underline{\boldsymbol{d}}$ a filtration of $\underline{\dim}\, M$. We want to define reflections on a flag $\boldsymbol{U}\in\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$. Let a be a sink and let $\boldsymbol{U}\in\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$. Then, for each i, we have the following commutative diagram with exact rows.

$$\begin{tikzcd}
0 \arrow[r] & (S_a^+U^{i-1})_a \arrow[r] \arrow[d, "f"] & \bigoplus U_j^{i-1} \arrow[r, "\phi_a^{U^{i-1}}"] \arrow[d] & \operatorname{Im}\phi_a^{U^{i-1}} \arrow[r] \arrow[d, "g"] & 0 \\
0 \arrow[r] & (S_a^+U^{i})_a \arrow[r] & \bigoplus U_j^{i} \arrow[r, "\phi_a^{U^{i}}"'] & \operatorname{Im}\phi_a^{U^{i}} \arrow[r] & 0
\end{tikzcd}$$

By definition, g and the map in the middle are injective. Therefore, f is injective. This immediately yields that $S_a^+\boldsymbol{U}$ is a new quiver flag of $S_a^+M=S_a^+U^\nu$. The problem is that the dimension of $S_a^+U^i$ is dependent on the rank of $\phi_a^{U^i}$. This motivates the next definition. Recall that $d_a-\operatorname{rank}\phi_a^X=\dim\operatorname{Hom}(X,S_a)$ for a representation X of dimension vector $\underline{d}$.

Definition 5.2. Let a be a sink, $\underline{d}$ a dimension vector and s an integer. Define

$$\operatorname{Rep}_Q(\underline{d})\,\langle a\rangle^s := \left\{\, M\in\operatorname{Rep}_Q(\underline{d}) \;\middle|\; \dim\operatorname{Hom}(M,S_a)=s \,\right\}.$$

Let $\underline{\boldsymbol{d}}$ be a $(\nu+1)$-tuple of dimension vectors and $\boldsymbol{r}=(r^0,r^1,\dots,r^\nu)$ be a $(\nu+1)$-tuple of integers. For each representation M define

$$\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}\langle a\rangle^{\boldsymbol{r}} := \left\{ \boldsymbol{U}\in\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}} \;\middle|\; \dim\operatorname{Hom}(U^i,S_a)=r^i \right\}.$$

Moreover, let

$$\operatorname{Rep}_Q(\underline{d})\,\langle a\rangle := \operatorname{Rep}_Q(\underline{d})\,\langle a\rangle^0$$

and

$$\mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle a\rangle := \mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle a\rangle^{\mathbf{0}}.$$

Remark 5.3. Recall that a filtration $\underline{\boldsymbol{d}}$ of $\underline{\dim}\, M$ is a sequence of dimension vectors such that $\underline{d}^0 = 0$, $\underline{d}^\nu = \underline{\dim}\, M$ and that $\underline{d}^i \leq \underline{d}^{i+1}$. In order to know a filtration $\underline{\boldsymbol{d}}$ it is enough to know the terms $\underline{d}^1, \dots, \underline{d}^{\nu-1}$, since $\underline{d}^0$ is always 0 and $\underline{d}^\nu$ is always $\underline{\dim}\, M$. Therefore, we identify the $(\nu-1)$-tuple $(\underline{d}^1, \dots, \underline{d}^{\nu-1})$ with the $(\nu+1)$-tuple $\underline{\boldsymbol{d}}$.

Example 5.4. Let

$$Q = 1 \xrightarrow{\alpha} 2.$$

Consider the representation M given by $M_1 = M_2 = k^2$ and $M_\alpha = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. We have that $M \in \mathrm{Rep}_Q((2,2))\langle 2\rangle^1$. Now consider flags of type $((0,0),(1,1),(2,2))$, i.e. subrepresentations N of dimension vector $(1,1)$. We need two injective linear maps $f_1, f_2 \colon k^1 \to k^2$ making the following diagram commutative.

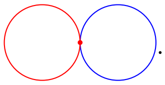
$$\begin{tikzcd}
k \arrow[r, "N_\alpha"] \arrow[d, "f_1"'] & k \arrow[d, "f_2"] \\
k^2 \arrow[r, "\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)"'] & k^2
\end{tikzcd}$$

We have the following situations.

- $N \in \mathrm{Gr}_Q\binom{M}{(1,1)}\langle 2\rangle^1$: This means that $N_\alpha = 0$. Therefore, we need that the image of f_1 is in the kernel of M_α, which is 1-dimensional. Hence, a subrepresentation in $\mathrm{Gr}_Q\binom{M}{(1,1)}\langle 2\rangle^1$ is given by $f_1 = \left(\begin{smallmatrix} 0 \\ 1 \end{smallmatrix}\right)$ and f_2 being an arbitrary inclusion. The point $f_1 = f_2 = \left(\begin{smallmatrix} 0 \\ 1 \end{smallmatrix}\right)$ is special, since for this inclusion we have that $M/N \cong S_1 \oplus S_2$ and otherwise $M/N \cong k \xrightarrow{1} k$.
- $N \in \mathrm{Gr}_Q\binom{M}{(1,1)}\langle 2\rangle^0$: This means that $N_\alpha \neq 0$. Therefore, we need that the image of f_1 is not in the kernel of M_α, which is 1-dimensional. Hence, a subrepresentation in $\mathrm{Gr}_Q\binom{M}{(1,1)}\langle 2\rangle^0$ is given by $f_1 = f_2 = \left(\begin{smallmatrix} 1 \\ x \end{smallmatrix}\right)$ for any $x \in k$.

The variety $\mathrm{Gr}_Q\binom{M}{(1,1)}$ consists therefore of two $\mathbb{P}^1_k$ glued together at one point. Graphically,

$$\mathrm{Gr}_Q\begin{pmatrix} M \\ (1,1) \end{pmatrix} = \mathrm{Gr}_Q\begin{pmatrix} M \\ (1,1) \end{pmatrix}\langle 2\rangle^1 \amalg \mathrm{Gr}_Q\begin{pmatrix} M \\ (1,1) \end{pmatrix}\langle 2\rangle^0 \cong$$



.

Note that the Grassmannian is neither irreducible nor smooth.

In order to get rid of $\boldsymbol{r}$ we define the following maps and then look at the fibres.

Definition 5.5. Let a be a sink, $\underline{d}$ a dimension vector and $M \in \mathrm{Rep}_Q(\underline{d})\langle a\rangle^s$ for an $s \in \mathbb{N}$. We have that $M \cong M' \oplus S_a^s$ for some element $M' \in \mathrm{Rep}_Q(\underline{d} - s\epsilon_a)\langle a\rangle$. Without loss of generality we can assume that $M = M' \oplus S_a^s$ and we set $\pi_a M := M'$. Obviously, $\pi_a M$ is unique up to isomorphism.

Now let $\underline{\boldsymbol{d}}$ be a filtration and $\boldsymbol{r} = (r^0, \dots, r^\nu)$ a $(\nu+1)$-tuple of integers. Define

$$\begin{aligned} \pi_a^{\boldsymbol{r}}\colon \quad \mathrm{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}} &\to \mathrm{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle \\ \boldsymbol{U} &\mapsto \boldsymbol{V} \qquad\qquad \text{where } V_j^i := \begin{cases} U_j^i & \text{if } j \neq a, \\ \operatorname{Im} \phi_a^{U^i} & \text{if } j = a. \end{cases} \end{aligned}$$

Remark 5.6. Note that $\pi_a M$ is $\iota_{a,M} S_a^- S_a^+ M$.

Example 5.7. Coming back to example 5.4 we see that π_2^1 collapses $\mathrm{Gr}_Q \binom{M}{(1,1)} \langle 2 \rangle^1$ to the point

$$\mathrm{Gr}_Q \begin{pmatrix} k^2 \overset{(1\ 0)}{\longrightarrow} k \\ (1,0) \end{pmatrix} \langle 2 \rangle .$$

The fibre of π_2^1 over this point is the vector space Grassmannian $\mathrm{Gr} \binom{k^2}{1}$, being isomorphic to $\mathbb{P}_k^1$.

We now introduce a little bit more notation. If $\boldsymbol{d}$ is a sequence, then denote by $\overleftarrow{\boldsymbol{d}}$ the sequence given by $(\overleftarrow{\boldsymbol{d}})^i = d^{\nu-i}$. Moreover, we define the sequence $\boldsymbol{e}$ by $e^i := d^\nu - d^{\nu-i}$. Therefore, if $\underline{\boldsymbol{d}}$ is a filtration of $\underline{d}^\nu$, then $\underline{\boldsymbol{e}}$ is a filtration of $\underline{d}^\nu$.

The fibre of the map $\pi_a^{\boldsymbol{r}}$ is a set of the following type.

Definition 5.8. Let $\boldsymbol{e} = (e^0, e^1, \dots, e^\nu)$ and $\boldsymbol{r} = (r^0, r^1, \dots, r^\nu)$ be sequences of non-negative integers such that $\boldsymbol{e} + \overleftarrow{\boldsymbol{r}}$ is a filtration. Let $A_{\nu+1}$ be the quiver

$$0 \to 1 \to 2 \to 3 \to \cdots \to \nu.$$

Then define

$$X^{\boldsymbol{r},\boldsymbol{e}} := \qquad k^{e^\nu + r^0} \twoheadrightarrow k^{e^{\nu-1}+r^1} \twoheadrightarrow \cdots \twoheadrightarrow k^{e^1 + r^{\nu-1}} \twoheadrightarrow k^{e^0 + r^\nu}.$$

Remark 5.9. The k-representation $X^{\boldsymbol{r},\boldsymbol{e}} \in \operatorname{rep}(A_{\nu+1}, k)$ is injective and its isomorphism class does not depend on the choice of the surjections.

Lemma 5.10. Let $\boldsymbol{e} = (e^0, e^1, \dots, e^\nu)$ and $\boldsymbol{r} = (r^0, r^1, \dots, r^\nu)$ be sequences of non-negative integers such that $\boldsymbol{e} + \overleftarrow{\boldsymbol{r}}$ is a filtration. Then $X^{\boldsymbol{r},\boldsymbol{e}}$ has a subrepresentation of dimension vector $\boldsymbol{r}$ if and only if $\boldsymbol{e}$ is a filtration of e^ν . Moreover, if k is a finite field with q elements, then the number of k-subrepresentations is given by

$$\# \mathrm{Gr}_{A_{\nu+1}} \binom{X^{\boldsymbol{r},\boldsymbol{e}}}{\boldsymbol{r}} = \prod_{i=0}^{\nu} \begin{bmatrix} e^{\nu-i} - e^{\nu-i-1} + r^i \\ r^i \end{bmatrix}_q .$$

In particular, this number is equal to 1 modulo q if and only if the set of subrepresentations is non-empty.

Proof. We prove this by induction on ν.

$\nu = 0$: There is a subspace of dimension r^0 of $k^{r^0+e^0}$ if and only if $e^0 \geq 0$ and, for k a finite field of cardinality q, the number of those is obviously $\begin{bmatrix} e^0 + r^0 \\ r^0 \end{bmatrix}_q$.

$\nu \geq 1$: If $(U^0, U^1, U^2, \dots, U^\nu)$ is a subrepresentation of dimension vector $\boldsymbol{r}$ of $X^{\boldsymbol{r},\boldsymbol{e}}$, then $(U^1, U^2, \dots, U^\nu)$ is a subrepresentation of dimension vector $(r^1, r^2, \dots, r^\nu)$ of $X^{(r^1,r^2,\dots,r^\nu),(e^0,e^1,\dots,e^{\nu-1})}$. Therefore, by induction, $e^i \leq e^{i+1}$ for $0 \leq i < \nu-1$ and $0 \leq e^0$. The preimage V of U^1 under the surjection from U^0 has dimension $r^1 + ((e^\nu + r^0) - (e^{\nu-1} + r^1)) = e^\nu - e^{\nu-1} + r^0$. Since $\boldsymbol{U}$ is a subrepresentation, we must have that $U^0 \subset V$. Therefore, $r^0 \leq e^\nu - e^{\nu-1} + r^0$ or equivalently $e^{\nu-1} \leq e^\nu$.

On the other hand, if $e^0 \geq 0$ and $e^i \leq e^{i+1}$ for all $0 \leq i < \nu$, then there is a subrepresentation $(U^1, U^2, \dots, U^\nu)$ of $X^{(r^1,r^2,\dots,r^\nu),(e^0,e^1,\dots,e^{\nu-1})}$ of dimension vector $(r^1, r^2, \dots, r^\nu)$ by induction. As before, the dimension of the preimage V of U^1 under the surjection from U^0 has dimension $e^\nu - e^{\nu-1} + r^0 \geq r^0$. If we choose now any subspace U^0 of dimension r^0 in V, then we obtain a subrepresentation of $X^{\boldsymbol{r},\boldsymbol{e}}$ of dimension vector $\boldsymbol{r}$.

If k is a finite field of cardinality q, then, by induction, we have that the number of subrepresentations of $X^{(r^1,r^2,\dots,r^\nu),(e^0,e^1,\dots,e^{\nu-1})}$ of dimension vector $(r^1, r^2, \dots, r^\nu)$ is equal to

$$\prod_{i=1}^{\nu} \begin{bmatrix} e^{\nu-i} - e^{\nu-i-1} + r^i \\ r^i \end{bmatrix}_q .$$

To complete such a subrepresentation to a subrepresentation of $X^{\boldsymbol{r},\boldsymbol{e}}$ we have to choose an r^0-dimensional subspace of an $(e^\nu - e^{\nu-1} + r^0)$-dimensional space. Therefore, the number of subrepresentations is equal to

$$\begin{bmatrix} e^\nu - e^{\nu-1} + r^0 \\ r^0 \end{bmatrix}_q \prod_{i=1}^{\nu} \begin{bmatrix} e^{\nu-i} - e^{\nu-i-1} + r^i \\ r^i \end{bmatrix}_q .$$

This yields the claim.

□

Theorem 5.11. Let a be a sink of Q, $\underline{\boldsymbol{d}}$ a filtration, $\boldsymbol{r}$ a $(\nu+1)$-tuple of non-negative integers and $M \in \operatorname{Rep}_Q(\underline{d}^\nu)$. Then

$$\pi_a^{\boldsymbol{r}} \colon \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}} \to \operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$$

is surjective and the fibre $(\pi_a^{\boldsymbol{r}})^{-1}(\boldsymbol{U})$ over any $\boldsymbol{U} \in \operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$ is isomorphic to $\operatorname{Gr}_{A_\nu} \binom{X^{\boldsymbol{r},\underline{\boldsymbol{e}}_a}}{\boldsymbol{r}}$, where $\underline{e}^{\nu-i} := \underline{d}^\nu - \underline{d}^i$. In particular the number of points in the fibre only depends on $\boldsymbol{r}$ and $\underline{\boldsymbol{d}}$ and not on $\boldsymbol{U}$.

Proof. Fix a flag $\boldsymbol{V} \in \operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$. Let $\boldsymbol{U} \in \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}}$. The flag $\boldsymbol{U}$ is in $(\pi_a^{\boldsymbol{r}})^{-1}(\boldsymbol{V})$ if and only if $U_j^i = V_j^i$ for all $j \neq a$ in which case $\operatorname{Im}(\Phi_a^{U^i}) = V_a^i$. Therefore, we only have to choose $U_a^i \subset M_a$ such that $V_a^i \subseteq U_a^i$, $U_a^{i-1} \subset U_a^i$ and $\dim U_a^i = d_a^i$ for all i. This is the same as choosing $\overline{U_a^i} \subset M_a/V_a^i$ such that $\theta^i(\overline{U_a^{i-1}}) \subset \overline{U_a^i}$ and $\dim \overline{U_a^i} = r^i$ if we denote by $\theta^i \colon M_a/V_a^{i-1} \to M_a/V_a^i$ the canonical projection. This is equivalent to finding a subrepresentation of

$$M_a/V_a^0 \to M_a/V_a^1 \to \cdots \to M_a/V_a^\nu$$

of dimension vector $\boldsymbol{r}$. All the maps in this representation are surjective since $\boldsymbol{V}$ is a flag, therefore this representation of $A_{\nu+1}$ is isomorphic to $X^{\boldsymbol{r},\boldsymbol{e}}$. Since $\underline{\boldsymbol{d}}$ is a filtration of M we have that $\underline{\boldsymbol{e}}$ is a filtration. Therefore, $\mathrm{Gr}_{A_\nu}\binom{X^{\boldsymbol{r},\underline{\boldsymbol{e}}_a}}{\boldsymbol{r}}$ is non-empty by lemma 5.10 and $\pi_a^{\boldsymbol{r}}$ is surjective. $\square$

Now we are nearly ready to do reflections. The only thing left to define is what happens on a source. If b is a source in Q, then b is a sink in Q^{op}, so we just dualise everything. Denote by $D := \mathrm{Hom}_k(-, k)$.

Definition 5.12. Let $\boldsymbol{U} \in \mathrm{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ and let $\underline{e}^{\nu-i} = \underline{d}^\nu - \underline{d}^i$. Then define

$$\begin{aligned} \hat{D}\colon \quad \mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} &\to \mathrm{Fl}_{Q^{op}}\begin{pmatrix} DM \\ \underline{\boldsymbol{e}} \end{pmatrix} \\ \boldsymbol{U} &\mapsto (\hat{D}(\boldsymbol{U}))^i := \ker(DM \to D(U^i)) = D(M/U^i). \end{aligned}$$

Remark 5.13. Obviously, $\hat{D}^2 \cong \mathrm{id}$ and the map $\hat{D}$ is an isomorphism of varieties.

Definition 5.14. Let b be a source, $\underline{d}$ a dimension vector and s an integer. Define

$$\mathrm{Rep}_Q(\underline{d})\,\langle b\rangle^s := \left\{ M \in \mathrm{Rep}_Q(\underline{d}) \;\middle|\; \dim \mathrm{Hom}(S_b, M) = s \right\}.$$

Let $\underline{\boldsymbol{d}}$ be a $(\nu+1)$-tuple of dimension vectors and $\boldsymbol{r} = (r^0, r^1, \ldots, r^\nu)$ be a $(\nu+1)$-tuple of integers. For each representation M define

$$\mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle b\rangle^{\boldsymbol{r}} := \left\{ \boldsymbol{U} \in \mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} \;\middle|\; \dim \mathrm{Hom}(S_b, M/U^i) = r^i \right\}.$$

Moreover, let

$$\mathrm{Rep}_Q(\underline{d})\,\langle b\rangle := \mathrm{Rep}_Q(\underline{d})\,\langle b\rangle^0$$

and

$$\mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle b\rangle := \mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle b\rangle^{\boldsymbol{0}}.$$

Remark 5.15. Note that $\boldsymbol{U} \in \mathrm{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}\langle b\rangle^{\boldsymbol{r}}$ if and only if $\hat{D}\boldsymbol{U} \in \mathrm{Fl}_{Q^{op}}\binom{DM}{\underline{\boldsymbol{e}}}\langle b\rangle^{\boldsymbol{r}}$.

Now we state the main result on reflections.

Theorem 5.16. Let a be a sink of Q, $\underline{\boldsymbol{d}}$ be a filtration and $M \in \mathrm{Rep}_Q(\underline{d}^\nu)\,\langle a\rangle$. The map

$$\begin{aligned} S_a^+\colon \quad \mathrm{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix}\langle a\rangle &\to \mathrm{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M \\ \sigma_a \underline{\boldsymbol{d}} \end{pmatrix}\langle a\rangle \\ \boldsymbol{U} &\mapsto S_a^+ \boldsymbol{U} \end{aligned}$$

is an isomorphism of varieties with inverse $\hat{D} \circ S_a^+ \circ \hat{D} = S_a^-$.

Proof. First, we show that $S_a^+\boldsymbol{U}$ lies in the correct set. Let $\underline{e}^{\nu-i} = \underline{d}^{\nu} - \underline{d}^{i}$. For each i, we have the following commutative diagram with exact columns.

$$\begin{tikzcd}
 & 0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] & \\
0 \arrow[r] & (S_a^+U^i)_a \arrow[r] \arrow[d] & \bigoplus_{j\to a} U^i_j \arrow[r, "\phi_a^{U^i}"] \arrow[d] & U^i_a \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & (S_a^+M)_a \arrow[r] \arrow[d] & \bigoplus_{j\to a} M_j \arrow[r, "\phi_a^{M}"] \arrow[d] & M_a \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & (S_a^+M/S_a^+U^i)_a \arrow[r] \arrow[d] & \bigoplus_{j\to a} (M/U^i)_j \arrow[r, "\phi_a^{M/U^i}"] \arrow[d] & (M/U^i)_a \arrow[r] \arrow[d] & 0 \\
 & 0 & 0 & 0 &
\end{tikzcd}$$

The two top rows are exact since $\boldsymbol{U} \in \mathrm{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}\langle a\rangle$. By the snake lemma, we have that the bottom row is exact. Therefore, the map

$$(S_a^+M/S_a^+U^i)_a \to \bigoplus_{j\to a}(M/U^i)_j$$

is injective and hence $S_a^+(M)/S_a^+(U^i) \in \mathrm{Rep}_{\sigma_a Q}(\sigma_a(\underline{e}^{\nu-i}))\langle a\rangle$. The diagram also yields that $\hat{D}\circ S_a^+ \circ \hat{D} \circ S_a^+ = \mathrm{id}$. Since S_a^+ is a functor and all choices where natural, we have that S_a^+ gives a natural transformation between the functors of points of these two varieties. Therefore, it is a morphism of varieties.

Dually, $S_a^+ \circ \hat{D} \circ S_a^+ \circ \hat{D} = \mathrm{id}$. This concludes the proof. □

6. Reflection functors and Hall numbers

First we recall the definition of the Hall algebra. The main references for this are Ringel [Rin90a] and Hubery [Hub]. Let k be a finite field. Let $M, N, X \in \mathrm{rep}(Q,k)$ be three k-representations of Q. Then define

$$F^X_{MN} := \#\{\, U \le X \mid U \text{ subrepresentation}, U \cong N, X/U \cong M\,\}.$$

This is a finite number.

Let $\mathcal{H}_k(Q)$ be the $\mathbb{Q}$-vector space with basis $u_{[X]}$ where $[X]$ is the isomorphism class of X. For convenience we write u_X instead of $u_{[X]}$. Define

$$u_{[M]} \diamond u_{[N]} := \sum_{[X]} F^X_{MN} u_{[X]}.$$

Then $(\mathcal{H}(\mathcal{A}), +, \diamond)$ is an associative $\mathbb{Q}$-algebra with unit $1 = u_0$, the Ringel-Hall algebra or just Hall algebra. The composition algebra is the subalgebra $\mathcal{C}_k(Q)$ of $\mathcal{H}_k(Q)$ generated by the simple objects without self-extensions. Note that $\mathcal{H}_k(Q)$ and $\mathcal{C}_k(Q)$ are naturally graded by dimension vector.

To each vertex $i \in Q_0$ there is a simple object S_i given by $(S_i)_i = k$, $(S_i)_j = 0$ for $i \neq j$ and $(S_i)_\alpha = 0$ for all $\alpha \in Q_1$. We set $u_i := u_{S_i}$ for each $i \in Q_0$. If $w = (i_1, \ldots, i_r)$ is a word in vertices of Q, we define

$$u_w := u_1 \diamond \cdots \diamond u_r.$$

By definition, there are numbers F_w^X for each k-representation X of Q such that

$$u_w = \sum_X F_w^X u_X.$$

Let $k = \mathbb{F}_q$ be the finite field with q elements and Q a quiver. Let $w = (i_r, \ldots, i_1)$ be a word in vertices of Q. Define a filtration $\underline{\boldsymbol{d}}(w)$ by letting

$$\underline{d}(w)^k := \sum_{j=1}^{k} \epsilon_{i_k}.$$

Then we obviously have $F_w^X = \# \operatorname{Fl}_Q \binom{X}{\underline{\boldsymbol{d}}(w)}$. Therefore, coefficients in the Hall algebra are closely related to counting points of quiver flags over finite fields. In the following, we will use reflection functors to simplify the problem of counting the number of points modulo q. As an application, we will show that for a preprojective or preinjective representation X we have that $\# \operatorname{Fl}_Q \binom{X}{\underline{\boldsymbol{d}}} = 1 \mod q$ if $\operatorname{Fl}_Q \binom{X}{\underline{\boldsymbol{d}}}$ is non-empty.

Lemma 6.1. Let a be a sink of Q, k a field, $\underline{\boldsymbol{d}}$ a filtration and $M \in \operatorname{Rep}_Q(\underline{d}^\nu, k)$. Then

$$\# \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} = \sum_{\boldsymbol{r} \geq 0} \# \operatorname{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}, \boldsymbol{e}_a}}{\boldsymbol{r}} \# \operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$$

(on both sides we possibly have ∞).

Moreover, for each sequence of non-negative integers $\boldsymbol{r}$, if $\operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$ is non-empty, then so is $\operatorname{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}, \boldsymbol{e}_a}}{\boldsymbol{r}}$.

Proof. We have that

$$\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} = \coprod_{\boldsymbol{r} \geq 0} \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}}.$$

By theorem 5.11, we have for each sequence of non-negative integers $\boldsymbol{r}$ that

$$\# \operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}} = \# \operatorname{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}, \boldsymbol{e}_a}}{\boldsymbol{r}} \# \operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle.$$

By the same theorem we have that if $\operatorname{Fl}_Q \binom{\pi_a M}{\underline{\boldsymbol{d}} - \boldsymbol{r}\epsilon_a} \langle a \rangle$ is non-empty, then so is $\operatorname{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}, \boldsymbol{e}_a}}{\boldsymbol{r}}$. □

Lemma 6.2. Let a be a sink of Q, k a field, $\underline{\boldsymbol{d}}$ a filtration and $M \in \operatorname{Rep}_Q(\underline{d}^\nu, k) \langle a \rangle^s$. Let $\boldsymbol{r}_+ = \boldsymbol{r}_+(\underline{\boldsymbol{d}})$ be given as follows:

$$\begin{aligned} r_+^0 &:= 0; \\ r_+^i &:= \max\{0, (\sigma_a(\underline{d}^{i-1} - \underline{d}^i))_a + r_+^{i-1}\} \qquad \text{for } 0 < i < \nu; \\ r_+^\nu &:= s. \end{aligned}$$

Now let $\boldsymbol{r}$ be a sequence of integers. If $\operatorname{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a \rangle^{\boldsymbol{r}}$ is non-empty, then $\boldsymbol{r} \geq \boldsymbol{r}_+$.

Proof. Let $\boldsymbol{U} \in \mathrm{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} \langle a\rangle^{\boldsymbol{r}}$. By definition, $\mathrm{Hom}(U^i, S_a) = r^i$. We have

$$r^i = \operatorname{codim} \operatorname{Im} \Phi_a^{U^i} = \dim\ker \Phi_a^{U^i} + d_a^i - \sum_{j\to a} d_j^i = \dim\ker \Phi_a^{U^i} - (\sigma_a \underline{d}^i)_a.$$

We prove $r^i \geq r_+^i$ by induction on i. For $i = 0$ the claim is obviously true. Now let $0 \leq i \leq \nu - 2$. Obviously, $\dim\ker \Phi_a^{U^i} \leq \dim\ker \Phi_a^{U^{i+1}}$. Therefore,

$$r_+^i + (\sigma_a \underline{d}^i)_a \leq r^i + (\sigma_a \underline{d}^i)_a = \dim\ker \Phi_a^{U^i} \leq \dim\ker \Phi_a^{U^{i+1}} = r^{i+1} + (\sigma_a \underline{d}^{i+1})_a.$$

Hence, $r^{i+1} \geq \max\{0, (\sigma_a(\underline{d}^i - \underline{d}^{i+1}))_a + r_+^i\} = r_+^{i+1}$.

For r_+^ν note that, by definition, $U^\nu = M$ and therefore

$$r^\nu = \operatorname{codim} \operatorname{Im} \Phi_a^{U^\nu} = \operatorname{codim} \operatorname{Im} \Phi_a^M = s.$$

□

Remark 6.3. Note that $\boldsymbol{r}_+(\underline{\boldsymbol{d}} - \boldsymbol{r}_+(\underline{\boldsymbol{d}})\epsilon_a) = 0$ since

$$\sigma_a(\underline{d}^i - \underline{d}^{i-1})_a + r_+^i(\underline{\boldsymbol{d}}) - r_+^{i-1}(\underline{\boldsymbol{d}}) \geq r_+^i(\underline{\boldsymbol{d}}) - r_+^i(\underline{\boldsymbol{d}}) = 0.$$

For any filtration $\underline{\boldsymbol{d}}$ of some representation M it is enough to remember the terms

$$(\underline{d}^1, \ldots, \underline{d}^{\nu-1})$$

since we always have $\underline{d}^0 = 0$ and $\underline{d}^\nu = \underline{\dim}\, M$. Note that the rule to construct r_+^i for $0 < i < \nu$ depends neither on $\underline{d}^0$ nor on $\underline{d}^\nu$. Therefore, we can define

$$S_a^+ \underline{\boldsymbol{d}} = S_a^+(\underline{d}^1, \ldots, \underline{d}^{\nu-1}) := (\sigma_a \underline{d}^1 + r_+^1 \epsilon_a, \ldots, \sigma_a \underline{d}^{\nu-1} + r_+^{\nu-1}).$$

If $\underline{\boldsymbol{d}}$ is a filtration of M, then $S_a^+ \underline{\boldsymbol{d}}$ is a filtration of $S_a^+ M$ if and only if $(S_a^+ \underline{\boldsymbol{d}})^{\nu-1} \leq \underline{\dim}\, S_a^+ M$.

Corollary 6.4. *Let a be a sink, k a field, $\underline{\boldsymbol{d}}$ a filtration and $M \in \mathrm{Rep}_Q(\underline{d}^\nu, k)\langle a\rangle^s$. Then*

$$\# \mathrm{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} = \sum_{\boldsymbol{r} \geq 0} \# \mathrm{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}+\boldsymbol{r}_+, \boldsymbol{e}_a}}{\boldsymbol{r}+\boldsymbol{r}_+} \# \mathrm{Fl}_{\sigma_a Q} \binom{S_a^+ M}{S_a^+ \underline{\boldsymbol{d}} + \boldsymbol{r}\epsilon_a} \langle a\rangle.$$

In particular, if k is a finite field of cardinality q, we have

$$\# \mathrm{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} = \sum_{\boldsymbol{r} \geq 0} \# \mathrm{Fl}_{\sigma_a Q} \binom{S_a^+ M}{S_a^+ \underline{\boldsymbol{d}} + \boldsymbol{r}\epsilon_a} \langle a\rangle \mod q.$$

Proof. By lemmas 6.1 and 6.2 we obtain that

$$\# \mathrm{Fl}_Q \binom{M}{\underline{\boldsymbol{d}}} = \sum_{\boldsymbol{r} \geq 0} \# \mathrm{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}+\boldsymbol{r}_+, \boldsymbol{e}_a}}{\boldsymbol{r}+\boldsymbol{r}_+} \# \mathrm{Fl}_Q \binom{\pi_a^s M}{\underline{\boldsymbol{d}} - (\boldsymbol{r}+\boldsymbol{r}_+)\epsilon_a} \langle a\rangle.$$

Note that $\sigma_a(\underline{d}^i - (r^i + r_+^i)\epsilon_a) = (S_a^+ \underline{\boldsymbol{d}})^i + r^i \epsilon_a$ for all $0 < i < \nu$. Therefore, theorem 5.16 yields that

$$\mathrm{Fl}_Q \binom{\pi_a^s M}{\underline{\boldsymbol{d}} - (\boldsymbol{r}+\boldsymbol{r}_+)\epsilon_a} \langle a\rangle \cong \mathrm{Fl}_{\sigma_a Q} \binom{S_a^+ M}{S_a^+ \underline{\boldsymbol{d}} + \boldsymbol{r}\epsilon_a} \langle a\rangle.$$

This proves the first claim.

Now let k be a finite field of cardinality q. If $\mathrm{Gr}_{A_\nu} \binom{X^{\boldsymbol{r}+\boldsymbol{r}_+, \boldsymbol{e}_a}}{\boldsymbol{r}+\boldsymbol{r}_+}$ is non-empty, then its number is one modulo q by lemma 5.10. The second part of lemma 6.1

yields that whenever $\operatorname{Fl}_Q\binom{\pi_a^s M}{\underline{\boldsymbol{d}}-(\boldsymbol{r}+\boldsymbol{r}_+)\epsilon_a}\langle a\rangle$ is non-empty, then $\operatorname{Gr}_{A_\nu}\binom{X^{\boldsymbol{r}+\boldsymbol{r}_+,\boldsymbol{e}_a}}{\boldsymbol{r}+\boldsymbol{r}_+}$ is non-empty. This finishes the proof. □

We obtain the following.

Theorem 6.5. Let a be a sink, k a field, $\underline{\boldsymbol{d}}$ a filtration and $M \in \operatorname{Rep}_Q(\underline{d}^\nu, k)\langle a\rangle^s$. Then $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ is empty if and only if $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}}$ is.

Moreover, if $k = \mathbb{F}_q$ is a finite field, then

$$\#\operatorname{Fl}_Q\begin{pmatrix} M\\ \underline{\boldsymbol{d}}\end{pmatrix} = \#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}\end{pmatrix} \mod q.$$

Proof. By corollary 6.4 we obtain that

$$\#\operatorname{Fl}_Q\begin{pmatrix} M\\ \underline{\boldsymbol{d}}\end{pmatrix} = \sum_{\boldsymbol{r}\geq 0}\#\operatorname{Gr}_{A_\nu}\begin{pmatrix} X^{\boldsymbol{r}+\boldsymbol{r}_+,\boldsymbol{e}_a}\\ \boldsymbol{r}+\boldsymbol{r}_+\end{pmatrix}\#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a\end{pmatrix}\langle a\rangle .$$

Note that $S_a^+\underline{\boldsymbol{d}}$ is a filtration of $S_a^+ M$ if and only if $(S_a^+\underline{\boldsymbol{d}})^{\nu-1} \leq \underline{\dim}\, S_a^+ M$. Therefore, if $S_a^+\underline{\boldsymbol{d}}$ is not a filtration of $S_a^+ M$, then each $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a}\langle a\rangle$ is empty for all $\boldsymbol{r}\geq 0$ and hence, so is $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$. In this case, we also have that $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}}$ is empty. Both claims follow.

Assume now that $S_a^+\underline{\boldsymbol{d}}$ is a filtration of $S_a^+ M$. We have that

$$\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}\end{pmatrix} \cong \operatorname{Fl}_{\sigma_a Q^{op}}\begin{pmatrix} DS_a^+ M\\ \underline{\dim}\, S_a^+ M - \overleftarrow{S_a^+\underline{\boldsymbol{d}}}\end{pmatrix}$$

via $\hat{D}$. Let $\underline{\boldsymbol{f}} := \underline{\dim}\, S_a^+ M - \overleftarrow{S_a^+\underline{\boldsymbol{d}}}$. By using lemma 6.1 we obtain that

$$\#\operatorname{Fl}_{\sigma_a Q^{op}}\begin{pmatrix} DS_a^+ M\\ \underline{\boldsymbol{f}}\end{pmatrix} = \sum_{\boldsymbol{r}\geq 0}\#\operatorname{Gr}_{A_\nu}\begin{pmatrix} X^{\overleftarrow{\boldsymbol{r}},(S_a^+\underline{\boldsymbol{d}})_a}\\ \overleftarrow{\boldsymbol{r}}\end{pmatrix}\#\operatorname{Fl}_{\sigma_a Q^{op}}\begin{pmatrix} DS_a^+ M\\ \underline{\boldsymbol{f}} - \overleftarrow{\boldsymbol{r}}\,\epsilon_a\end{pmatrix}\langle a\rangle .$$

Moreover, by the same lemma we have for each $\boldsymbol{r}\geq 0$ that if $\operatorname{Fl}_{\sigma_a Q^{op}}\binom{DS_a^+ M}{\underline{\boldsymbol{f}}-\overleftarrow{\boldsymbol{r}}\epsilon_a}\langle a\rangle$ is non-empty, then $\operatorname{Gr}_{A_\nu}\binom{X^{\overleftarrow{\boldsymbol{r}},(S_a^+\underline{\boldsymbol{d}})_a}}{\overleftarrow{\boldsymbol{r}}}$ is non-empty. Using $\hat{D}$ yields

$$\operatorname{Fl}_{\sigma_a Q^{op}}\begin{pmatrix} DS_a^+ M\\ \underline{\boldsymbol{f}} - \overleftarrow{\boldsymbol{r}}\,\epsilon_a\end{pmatrix}\langle a\rangle \cong \operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a\end{pmatrix}\langle a\rangle .$$

Combining these equalities, we have that

$$\#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}\end{pmatrix} = \sum_{\boldsymbol{r}\geq 0}\#\operatorname{Gr}_{A_\nu}\begin{pmatrix} X^{\overleftarrow{\boldsymbol{r}},(S_a^+\underline{\boldsymbol{d}})_a}\\ \overleftarrow{\boldsymbol{r}}\end{pmatrix}\#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M\\ S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a\end{pmatrix}\langle a\rangle .$$

Therefore, $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}}$ is empty if and only if for all $\boldsymbol{r}\geq 0$ we have that the variety $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a}\langle a\rangle$ is empty. The same is true for $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ and this proves the first claim.

Now let k be a finite field with q elements. By the first part, if $\operatorname{Fl}_{\sigma_a Q}\binom{S_a^+ M}{S_a^+\underline{\boldsymbol{d}}+\boldsymbol{r}\epsilon_a}\langle a\rangle$ is non-empty, then $\operatorname{Gr}_{A_\nu}\binom{X^{\overleftarrow{\boldsymbol{r}},(S_a^+\underline{\boldsymbol{d}})_a}}{\overleftarrow{\boldsymbol{r}}}$ is non-empty. Therefore, lemma 5.10 yields that

$$\#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M \\ S_a^+ \underline{\boldsymbol{d}} \end{pmatrix} = \sum_{\boldsymbol{r}\geq 0} \#\operatorname{Fl}_{\sigma_a Q}\begin{pmatrix} S_a^+ M \\ S_a^+ \underline{\boldsymbol{d}} + \boldsymbol{r}\epsilon_a \end{pmatrix} \langle a\rangle \mod q.$$

By corollary 6.4 this is equal to $\#\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$. This finishes the proof. □

Remark 6.6. The Coxeter functor C^+ is by definition the composition of reflection functors associated to an admissible ordering $(a_1, \ldots, a_n)$ of Q. The action on a filtration, which we also denote by C^+, is given by $C^+\underline{\boldsymbol{d}} := S_{a_n}^+ \ldots S_{a_1}^+ \underline{\boldsymbol{d}}$. It is not clear that C^+ on a filtration does not depend on the choice of the admissible ordering.

We immediately obtain the following.

Corollary 6.7. Let M be a preprojective k-representation and let $\underline{\boldsymbol{d}}$ be a filtration of $\underline{\dim}\, M$. Take $r \geq 0$ such that $(C^+)^r M = 0$.

Then $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ is non-empty if and only if we have that $(C^+)^r \underline{\boldsymbol{d}} = 0$ and that for every intermediate sequence w of admissible sink reflections $S_w^+ \underline{\boldsymbol{d}}$ is a filtration of $S_w^+ M$. In particular, this depends only on the isomorphism class of M and the filtration $\underline{\boldsymbol{d}}$, but not on the choice of M or the field k.

Moreover, if k is a finite field with q elements, then $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ non-empty implies that

$$\#\operatorname{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} = 1 \mod q.$$

Proof. Using remark 6.3 we obtain that for each reflection at a sink a of Q we have that $S_a^+ \underline{\boldsymbol{d}}$ is again a filtration of $S_a^+ M$ if and only if $(S_a^+ \underline{\boldsymbol{d}})^{\nu-1} \leq \underline{\dim}\, S_a^+ M$. If this is not the case, then the quiver flag is empty by theorem 6.5. Therefore, if the quiver flag is non-empty, then for every intermediate sequence w of admissible sink reflections we have that $S_w^+ \underline{\boldsymbol{d}}$ is a filtration of $S_w^+ M$. We call this condition (*).

Assume that (*) holds. Iteratively applying theorem 6.5 we have that $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ is empty if and only if $\operatorname{Fl}_Q\binom{(C^+)^r M}{(C^+)^r \underline{\boldsymbol{d}}} = \operatorname{Fl}_Q\binom{0}{(C^+)^r \underline{\boldsymbol{d}}}$ is empty. There is only one filtration of the 0 representation, namely $(0, 0, \ldots, 0)$. Therefore, $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ is non-empty if and only if $(C^+)^r \underline{\boldsymbol{d}} = 0$. This proves the first part since we already have seen that if (*) does not hold, then $\operatorname{Fl}_Q\binom{M}{\underline{\boldsymbol{d}}}$ is empty.

Assume now that k is a finite field with q elements. If (*) does not hold, then the quiver flag is empty and the claim holds. Assume therefore that (*) holds. As before, applying theorem 6.5 yields that

$$\#\operatorname{Fl}_Q\begin{pmatrix} M \\ \underline{\boldsymbol{d}} \end{pmatrix} = \#\operatorname{Fl}_Q\begin{pmatrix} (C^+)^r M \\ (C^+)^r \underline{\boldsymbol{d}} \end{pmatrix} = \#\operatorname{Fl}_Q\begin{pmatrix} 0 \\ (C^+)^r \underline{\boldsymbol{d}} \end{pmatrix} \mod q.$$

There is only one filtration of the zero representation, namely $(0, 0, \ldots, 0)$, and the number of flags of this type is obviously equal to one. This concludes the proof. □

7. Dynkin case

In this section let Q be a Dynkin quiver. We first introduce the generic Hall algebra $\mathcal{H}_q(Q)$ and the composition monoid $\mathcal{CM}(Q)$ and then use the results of the previous section to show that $\mathcal{H}_0(Q) \cong \mathcal{CM}(Q)$, where the isomorphism is given by sending u_i to S_i.

Since Q is Dynkin, every representation is preprojective. Moreover, indecomposable representations of Q are in bijection with the set of positive roots Δ_+ of the Lie algebra corresponding to the underlying Dynkin diagram. An isomorphism class is therefore given by a function from Δ_+ to $\mathbb{N}$ with finite support. We denote this set by Φ. For each element $\mu \in \Phi$ and each field k we can choose a k-representation $M(\mu, k)$ having isomorphism class μ.

Hall polynomials exist with respect to Φ, as shown by Ringel [Rin90b]. More precisely, for $\mu, \nu, \xi \in \Phi$ there is a polynomial $f^{\xi}_{\mu\nu}(q) \in \mathbb{Z}[q]$ such that for each finite field k with q_k elements we have

$$F^{M(\xi,k)}_{M(\mu,k)M(\nu,k)} = f^{\xi}_{\mu\nu}(q_k).$$

We define the generic Hall algebra $\mathcal{H}_q(Q)$ to be the free $\mathbb{Z}[q]$-module with basis $\{ u_\alpha \mid \alpha \in \Phi \}$ and multiplication given by:

$$u_\mu \diamond u_\nu = \sum_{\xi} f^{\xi}_{\mu\nu}(q) u_\xi.$$

The generic composition algebra $\mathcal{C}_q(Q)$ is the subalgebra of $\mathcal{H}_q(Q)$ generated by the simple representations without self-extensions, or more precisely their isomorphism classes. For an acyclic quiver theses are exactly the u_i. If the quiver is fixed, then we often write $\mathcal{H}_q$ and $\mathcal{C}_q$ instead of $\mathcal{H}_q(Q)$ and $\mathcal{C}_q(Q)$. Moreover, for convenience we identify for any representation $M \cong M(\alpha, k)$, u_M with u_α and f^X_{MN} with $f^{\xi}_{\mu\nu}(q)$.

When calculating Hall polynomials, certain quantum numbers appear. Let R be some commutative ring and let $q \in R$. Usually R will be $\mathbb{Z}[q]$, the polynomial ring in one variable. We define for $r, n \in \mathbb{N}$, $0 \le r \le n$:

$$\begin{aligned}
[n]_q &:= 1 + q + \dots + q^{n-1} \\
[n]_q! &:= \prod_{i=1}^{n} [i]_q \\
\begin{bmatrix} n \\ r \end{bmatrix}_q &:= \frac{[n]_q!}{[r]_q![n-r]_q!}.
\end{aligned}$$

Obviously, $\begin{bmatrix} n \\ r \end{bmatrix}_0 = 1$.

Fix an algebraically closed field k. We say that a representation M degenerates to N, $M \le_{\deg} N$, if $\mathcal{O}_N \subseteq \overline{\mathcal{O}_M}$, where we take the closure in the Zariski topology.

For two arbitrary sets $U \subseteq \operatorname{Rep}(\underline{d}), V \subseteq \operatorname{Rep}(\underline{e})$ we define

$$\begin{aligned}
\mathcal{E}(U, V) := \{M \in \operatorname{Rep}(\underline{d} + \underline{e}) \mid \exists\, A \in U, B \in V \text{ and a short exact sequence} \\
0 \to B \to M \to A \to 0\}.
\end{aligned}$$

The multiplication on closed irreducible $\mathrm{GL}_{\underline{d}}$-stable respectively $\mathrm{GL}_{\underline{e}}$-stable subvarieties $\mathcal{A} \subseteq \operatorname{Rep}(\underline{d}), \mathcal{B} \subseteq \operatorname{Rep}(\underline{e})$ is defined as:

$$\mathcal{A} * \mathcal{B} := \mathcal{E}(\mathcal{A}, \mathcal{B}).$$

The set of closed irreducible subvarieties of nilpotent representations with this multiplication is a monoid with unit $\operatorname{Rep}(\underline{0})$, the generic extension monoid $\mathcal{M}(Q)$. The composition monoid $\mathcal{CM}(Q)$ is the submonoid generated by the orbits of simple representations without self-extensions. All this is due to Reineke [Rei02]. For any word $w = (i_1, \dots, i_r)$ in vertices of Q we define $\mathcal{A}_w := \mathcal{O}_{S_1} * \dots * \mathcal{O}_{S_r}$. This is an element of $\mathcal{CM}(Q)$.

We can now use the machinery we developed in the previous section to prove that, for Q a Dynkin quiver, the generic composition algebra specialised at $q = 0$ and the composition monoid are isomorphic.

Proposition 7.1. Let X be a k-representation of Q and w a word in vertices of Q. Then the condition that X has a filtration of type w only depends on w and $[X] \in \Phi$ and not on the choice of X or the field k.

Moreover, we have that

$$u_w = \sum_{[X] \in [\mathcal{A}_w]} u_{[X]} \in \mathcal{H}_0(Q).$$

Proof. Since all representations of Q are preprojective, the first part of the statement follows directly from corollary 6.7. Therefore, the sum in the second part is well-defined (i.e. the set $[\mathcal{A}_w]$ does not depend on the field).

If k is a finite field with q elements, corollary 6.7 also yields that

$$F_w^X = \#\operatorname{Fl}_Q \binom{X}{\underline{\boldsymbol{d}}(w)} = \begin{cases} 1 \mod q & \text{if } X \in \mathcal{A}_w, \\ 0 & \text{else.} \end{cases}$$

Since $F_w^X = f_w^{[X]}(q)$ and we just showed that this is one modulo q for all prime powers q we have that

$$f_w^{[X]}(0) = \begin{cases} 1 & \text{if } [X] \in [\mathcal{A}_w], \\ 0 & \text{else.} \end{cases}$$

This yields the claim. □

We obtain the main theorem for the Dynkin case.

Theorem 7.2. The map

$$\begin{aligned} \Psi\colon \quad \mathbb{Q}\mathcal{M}(Q) &\to \mathcal{H}_0(Q) \\ \mathcal{A} &\mapsto \sum_{[M] \in [\mathcal{A}]} u_{[M]} \end{aligned}$$

is an isomorphism of $\mathbb{Q}$-algebras.

Proof. Note that for Q Dynkin we have that $\mathcal{M}(Q) \cong \mathcal{CM}(Q)$ and $\mathcal{H}_q(Q) \cong \mathcal{C}_q(Q)$. Therefore, for each $\mathcal{A} \in \mathcal{M}(Q)$ there is a word w in vertices of Q such that $\mathcal{A} = \mathcal{A}_w$. In the previous proposition we showed that the map sending $\mathcal{A}_w$ to

$$\Psi(\mathcal{A}_w) = \sum_{[M] \in [\mathcal{A}_w]} u_{[M]} = u_w$$

is well-defined. Therefore, Ψ is a homomorphism, since

$$\Psi(\mathcal{A}_w * \mathcal{A}_v) = \Psi(\mathcal{A}_{wv}) = u_{wv} = u_w \diamond u_v = \Psi(\mathcal{A}_w) \diamond \Psi(\mathcal{A}_v).$$

Ψ is surjective since it is a homomorphism, and the generators u_i of $\mathcal{H}_0(Q)$ are in the image of Ψ. More precisely, $\Psi(\mathcal{O}_{S_i}) = u_i$. Obviously, Ψ is a graded morphism of graded algebras. The dimension of the $\underline{d}$-th graded part of $\mathbb{Q}\mathcal{M}(Q)$ is the same as the dimension of the $\underline{d}$-th graded part of $\mathcal{H}_0(Q)$, namely the number of isomorphism classes of representations of dimension vector $\underline{d}$. Since each graded part is finite dimensional and Ψ is surjective, we have that Ψ is an isomorphism. □

8. Further work

In an upcoming paper, we show that if Q is an acyclic extendend Dynkin quiver, then

$$\begin{aligned}\Phi\colon \quad \mathcal{C}_0(Q) &\to \mathcal{CM}(Q)\\ u_i &\to S_i\end{aligned}$$

is a homomorphism and give generators for its non-trivial kernel. We do this by a close analysis of the geometric version of reflection functors and the result of a previous paper on the Hall algebra of an oriented cycle.
